

Membrane Roof for a Tennis Court

Master-Thesis

A thesis submitted in partial fulfillment
of the requirements for the degree of

Master Membrane Structures

submitted to

Anhalt University of Applied Sciences

Faculty of Architecture,
Facility Management and Geo Information

by

João Jorge Fernandes Abrantes

13 May 1980, Porto, Portugal

Matriculation number: 4053867

Submission: 24th July 2014

First Tutor: Prof. Dr.-Ing. Robert Off

Second Tutor: M.Eng. Atisit Sabmeethavorn

I hereby declare that the work presented in this Master Thesis, entitled

Membrane Roof for Tennis Court

is entirely my own and that I did not use any sources or auxiliary means other than those referenced.

Porto, Portugal. June 2014

Acknowledgment

I am thankful to God for the many blessings that I have in my life.

All my gratitude to my parents, brother and girlfriend for the support during the Master Course.

To Mr. Rudolf Bergermann, founding partner of Schlaich Bergermann und Partner, who taught me almost everything about Structural Engineering.

To the tutors of this Master Thesis, for having accepted to guide me.

1 Introduction

1. Introduction

Tennis is a popular sport which can be played by any social class. It is an Olympic sport and the game reaches fans all over the world. There is a professional competition, which is played in different countries around the world, called ATP-Tour. The four major events of this Tour are the Australian Open, the French Open also known as Roland Garros, Wimbledon in the UK and the US Open. These events are usually covered by the media worldwide.

With the increase in the last years of the media coverage and the increase of the number of tennis fans, weather conditions have turned out to be a key factor for the success of the events. TV coverage cannot depend on weather conditions. Most of the events are played without a roof cover, which sometimes does not help the media work, the comfort of the spectators and the success of the tennis events.

In the last years, with the increase of tennis fans and the demands of media coverage, there has been taken into consideration the design of new roofs for tennis courts. The climate change and unpredictability of the weather conditions during the tennis events have also contributed to the design of new tennis court roofs.

Membrane roof structures are therefore a solution to be taken into account for the design of new tennis stadium roofs because they are light weight, translucent, economic, architecturally pleasant, UV and weather resistant.

Light weight is a decisive criteria, because the new roofs can be constructed on existing buildings which are not prepared to carry extra heavy loads. In the case that they are constructed without touching the existing buildings, being light weight is also an advantage for long spans.

Translucency benefits the court atmosphere and the players' performance, reducing the use of artificial lights.

Depending on the structural system and span, membrane structures can be economical and cost competitive compared to other materials.

The design of new roofs for tennis courts give also the opportunity to the design of new retractable roofs. These retractable roofs can be open during good weather and rapidly closed during bad weather.

"The famed Rod Laver Arena was the first ever sports stadium with a retractable roof when it was opened on 11th January, 1988." (Source: <http://www.tennisearth.com>) It is place of the Australian Open.

Figure 1 – Rod Laver Arena Retractable Roof in Australia (Source: www.tennisticketnews.com)

The completed roof of the Rod Laver Arena has two rolling sections, each supported by steel trusses. The roof opens or closes with a speed of 1.3 meters per minute (Source: <http://www.rodlaverarena.com.au/>), taking 20 minutes complete the movement. The retractable has proved along the years to be a great help to the players when the temperatures drop or dramatically rise.

The Hisense Arena is located also in Melbourne, with a maximum capacity of 11000 people and the arena construction was completed in 2000. Is one of the few tennis arenas with a retractable roof.

A new design for the Margaret Court in the Melbourne Park has been proposed in 2012, namely a new retractable roof for the 7,500-seat Arena, which should be ready in 2015.

Figure 2 – Margaret Court Arena Redevelopment (Source: www.austadiums.com)

Gerry Weber Stadium is an indoor sports arena, located in Halle, in Germany. It is one of the first membrane retractable roof of a sports venue ever build. The outer roof is made of a pvc coated polyester fabric and the inner roof made of ETFE Cushions. The inner roof is made of two rolling sections that drive under the outer roof. The capacity of the arena is 12,300 people and it was opened in 1992. The tennis event Gerry Weber open is played in this stadium.

Figure 3 - Gerry Weber Stadium with ETFE Retractable Roof (Source: www.skyscrapercity.com)

The Rothenbaum retractable membrane roof was constructed in 1999 in Germany and the membrane opens from a single point to the edges, covering the tennis court. The process of opening and closing takes about five minutes. The same system is used for the retractable roof of the football stadium roof in Warsaw and can only be done at temperatures above five degrees, with a low wind speed and not during rain. This aspect is the main disadvantage of this kind of retractable systems, because during the process of opening or closing, the movable membrane is not under tension. It can act as a sail during the process of opening or closing, introducing very high forces in the existing structure due to wind loads, for which the structure is usually not dimensioned for.

Figure 4 – Rothenbaum Tennis Court – Retractable Roof (Source: www.hamburg-web.de)

The steel roof of the Qi Zhong Stadium is composed by eight sliding petal-shaped pieces that close in eight minutes. The capacity of the stadium is 15,000 people. The stadium was constructed to host the ATP World Tour Finals between 2005 and 2008.

The stadium can host other international sport events such as basketball, volleyball, ping pong, or gymnastics. [Source: Wikipedia]

Figure 5 – Qi Zhong Stadium – Retractable Roof (Source: www.tennisearth.com)

The “Magic Box” or “La Caja Mágica” in Madrid, also known as the Manzanares Park Tennis Center, is a sports center located at the Park Manzanares, used for the Madrid Masters tournament of the ATP Tour. It was opened in 2009. There is a series of retractable roofs at this sport center, but none of them has a membrane roof.

Figure 6 – Magic Box Stadium in Madrid – Retractable Roof (Source: www.nytimes.com)

The membrane roof of the center court in Wimbledon has been designed to “maintain pre-existing levels of light and air to the court when the roof is open, and when closed, an air flow system removes condensation from within the bowl to provide good court surface conditions conducive to the playing of tennis”. (Source: <http://www.wimbledon.com/>)

The retractable roof is made of two parts and it folds like a “concertina”. The roof closes in eight to ten minutes when bad weather occurs. It was built in 2009 and the structural translucent fabric covers 5,200 square meters.

Figure 7 – Centre Court Wimbledon – Retractable Roof (Source: www.nytimes.com)

There are plans to build new retractable roofs for the tennis court number one in Wimbledon, for the Center Tennis Court in Roland Garros and US Open. Thus, there is the possibility and the opportunity of building lightweight membrane structures with structural fabric.

The present work focus on the use of pvc coated polyester fabric for a roof cover of a tennis court. The retractable inner ETFE roof mechanical system will be not presented in this work, neither the textile façade of the proposed stadium will be considered.

The present Master-Thesis pretends to show that the use of the structural system “spoked wheel roof”, well known and constructed in many football stadium roofs, can also be applied to tennis courts and as an almost rectangular shape. It will be treated in this work as “Modified Spoked Wheel System”.

A “new” material, PVDF Foil, will be presented as potential structural material and analysed as an alternative to ETFE.

2 Design Process

2. Design Process

2.1 Architecture

The structural system “Modified Spoked Wheel System” determines into a certain degree the aesthetical appearance of the stadium roof. The valley and ridge cables together with the membrane geometry give the rhythm of the structure. The v-shaped columns are bonded together with the geometry of the valley and ridge cables and membrane.

The Etfе – Cushions “fly” above the tennis ground giving the idea of a sky with clouds, letting natural light come in into the stadium. The Etfе Cushions give a sense of lightweight to the retractable roof. The pvc coated polyester fabric is a translucent material, allowing the spectators to have a natural light environment.

Figure 8 – Aerial View of Proposed Solution (Rendering: Miguel Cristina/João Abrantes)

The ETFE cushions inner roof are hanging on the outer membrane roof. The inner roof is made of two parts which slide under the outer roof. The outer membrane roof is a “modified spoked wheel system”, where the steel compression ring is parallel at only certain parts to the tension cable ring.

Figure 9 – Side View of Proposed Solution (Rendering: Miguel Cristina/João Abrantes)

Figure 10 – Front View of Proposed Solution (Rendering: Miguel Cristina /João Abrantes)

Figure 11 – Inner View of Proposed Solution (Rendering: Miguel Cristina/João Abrantes)

2.2 Formfinding

Through the Formfinding process an equilibrium of the geometry and structural elements is determined. Formfinding can be used for membrane structures, cables and also for steel structures. At an initial stage, the structure presents a deflection under dead load and under a predetermined prestress condition. After the reshape of the structural elements such as membrane, cables and steel, the deformation of the structural elements tend to decrease. An iterative process of finding a new form is then made and the structure deformation tend to zero, being usually a convergent solution. The initial prestress state of the membrane and cables determines the end geometry of the structural elements.

There are several methods to do the Formfinding process of a structure. The most common ones is the force-density method.

1) The force density method can be described as:

Figure 12 - Force Density - Point i Analysis (Source: Google images)

Non – linear Equations:

$$\begin{aligned}
 x: \frac{x_m - x_i}{l_a} s_a + \frac{x_j - x_i}{l_b} s_b + \frac{x_k - x_i}{l_c} s_c + \frac{x_l - x_i}{l_d} s_d - p_x &= 0 \\
 y: \frac{y_m - y_i}{l_a} s_a + \frac{y_j - y_i}{l_b} s_b + \frac{y_k - y_i}{l_c} s_c + \frac{y_l - y_i}{l_d} s_d - p_y &= 0 \\
 z: \frac{z_m - z_i}{l_a} s_a + \frac{z_j - z_i}{l_b} s_b + \frac{z_k - z_i}{l_c} s_c + \frac{z_l - z_i}{l_d} s_d - p_z &= 0
 \end{aligned}$$

Force Density: $q = \frac{s}{l}$

Linear Equations by defining the force density q:

$$\begin{aligned}
 x: (x_m - x_i)q_a + (x_j - x_i)q_b + (x_k - x_i)q_c + (x_l - x_i)q_d - p_x &= 0 \\
 y: (y_m - y_i)q_a + (y_j - y_i)q_b + (y_k - y_i)q_c + (y_l - y_i)q_d - p_y &= 0 \\
 z: (z_m - z_i)q_a + (z_j - z_i)q_b + (z_k - z_i)q_c + (z_l - z_i)q_d - p_z &= 0
 \end{aligned}$$

- 2) For the Membrane Formfinding, the stiffness of the membrane was reduced to a value near zero, so that the induced prestress together with the dead load defines the shape of the membrane. Once the geometry is updated, the stiffness can be set to “normal” stiffness of the fabric.
- 3) The stiffness of the steel cables were also set to a value near zero during the Formfinding process, being just adjusted the prestress level.
- 4) The initial geometry of the steel compression rings, given by the architecture, was changed in order to reduce the bending moments and reduce material. By reducing the bending moments, the cross section can be also reduced and the solution is more economical.

The initial bending moments Mz of the steel compression rings present a value of 1083 kNm. After an iterative process of form finding, the bending moments of the steel compression rings are 179 kNm. The reduction is dramatic showing that a Formfinding process leads also to economic solutions.

Figure 13 – Initial Geometry, before Formfinding $M_{z,max} = 1083$ kNm

Figure 14 – Corrected Geometry, after Formfinding $M_{z,max} = 179$ kNm

3 Materials

3. Materials

3.1 Membrane Roof PVC coated Polyester Fabric

These were the values adopted for the structural analysis:

Material	Type	Tensile Strength Zr,k		Tensile Stiffness EA		Shear Stiffness GA	Self Weight g
		Warp	Fill	Warp	Fill		
Ferrari 1202		N/5 cm	N/5 cm	MN	MN	MN	kN/m2
PVC/PES	III	5600	5600	1.0	0.7	0.07	0.010

For a construction design, material tests should be carried to define in a more accurate way the material characteristics.

3.2 ETFE Cushions

These were the values adopted for the structural analysis:

ETFE Film - material data (T=23 Degrees , monoaxial Test)							
Material	Thickness	Tensile Strength Fu,k	Yield Strength fy,k	Tensile Modulus E	Shear Modulus G	Poisson's Ratio	Density
		N/mm2	N/mm2	N/mm2	N/mm2	-	g/cm3
ETFE	250 µm	48	21	900	310	0,45	1,75

For a construction design, material tests should be carried to define in a more accurate way the material characteristics.

4 Structural Analysis

4. Structural Analysis

4.1 Software

The software used for the structural analysis is called SOFiSTiK. This finite element program is based on a modular basis where all modules interchange data and save their results in a common database in a binary format. The results in this database can be accessed either by graphical interactive modules or by modules that run in batch mode and have ASCII input.

The following modules are used:

- **AQUA** calculates the properties of cross sections of any shape and made of any material. The cross section properties for a static analysis are determined, as well as characteristic magnitudes for the calculation of normal and shear stresses.
- **ASE** calculates the static and dynamic effects of general loading on any type of structure. To start the calculations the user divides the structure to be analyzed into an assembly of individual elements interconnected at nodes (Finite Element Method). Possible types of elements are: haunched beams, springs, cables, truss elements, plane triangular or quadrilateral shell elements and three-dimensional continuum elements.

The program handles structures with rigid or elastic types of support. An elastic support can be applied to an area, a line or at nodal points. Rigid elements or skew supports can be taken into account.

ASE calculates the effects of nodal, line and block loads. The loads can be defined independently from the selected element mesh. The generation of loads from stresses of a primary loadcase allows the consideration of construction stages, redistribution and creep effects.

Nonlinear calculations enables the user to take the failure of particular elements into account, such as: cables in compression, uplifting of supported plates, yielding, and friction or crack effects for spring and foundation elements.

Nonlinear materials are available for three-dimensional and shell elements.

Geometrical nonlinear computations allow the investigation of 2nd and 3rd order theory effects by cable, beam and shell structures. In case of beam structures, the program can calculate warping torsion with up to 7 degrees of freedom per node.

The analysis of folded structures or shells with finite elements requires considerable experience. The user of ASE should therefore gather experience from simple examples before tackling more complicated structures. A check of the results through approximate engineering calculations is imperative.

The structural analysis of the membrane roof is based on a geometrically non-linear calculation.

The software ixForten 4000 is used for patterning and wind local analysis.

Cable Arrangement and Cross Section numbers for Upper and Lower Radial Cables, including Front and Back Edge Cables:

4.4 Loads Assumptions

4.4.1 Dead Load

Respectively for reinforced concrete and steel, using the section values and a unit weight of 25.0 kN/m³ and 78.5 kN/m³.

Extraordinary details of Structural Steelwork are considered with additional nodal loads (e.g. steel cast cable nodes). Further primary steel structure that is not modeled within the global model is considered as additional loads, linear or nodal onto the primary structure.

For Cables, using the section values and a unit weight of 83.0 kN/m³ (includes corrosion protection)

4.4.2 Prestress

Cable supported structures require a regular pre stressed initial stage. Therefore prestress is a regular part of all stages of investigations together with the dead load. All cables and membranes are regular pre stressed according to the results of the form finding process.

This needs to be considered for the determination of the cutting length of the cables and the fabrication geometry of the steel structure.

4.4.3 Live Load

The roof is considered Category H with a load of 0.4 kN/m², not accessible except for normal maintenance and repair. It is not to be superimposed with other extreme loads. Since the wind loads are much higher than the live load, the live load will not be taken into account in the structural analysis.

4.4.4 Temperature

The city of Oeiras in Portugal is located in the Zone B according to the EN 1991 1-5.

T_{max} (summer) : 40 Degrees

T_{min} (winter) : 0 Degrees

T_{in} (summer) : 25 Degrees

T_{in} (winter) : 18 Degrees

Uniform Variation:

Summer: $T = (40+2+25)/2 = 34.5$ Degrees

Winter: $T = (0+18)/2 = 9$ Degrees

4.4.5 Wind Load

(1) The basic wind velocity shall be calculated:

$$V_b = C_{dir} \cdot C_{season} \cdot V_{b,0}$$

$$C_{dir} = 1.0$$

$$C_{season} = 1.0$$

According to the National Annex to the Eurocode:

$$v_{b,0} = 30 \text{ m/s (Zone B – Near the Coast)}$$

$$v_b = 1.0 \cdot 1.0 \cdot 30 = 30 \text{ m/s}$$

(2) Peak Velocity Pressure

$$q_b = 0.5 \cdot \rho \cdot v_b^2 = 0.56 \text{ kN/m}^2$$

$$Z = 27.32 \text{ m (Maximum Roof Height – On the Safe Side)}$$

Terrain Category – II

$$q_p = C_e(Z) \cdot q_b = 3.0 \cdot 0.56 = 1.7 \text{ kN/m}^2$$

(3) Wind Pressure

a) Steel Structure Analysis – Global Analysis

$$F_w = C_s \cdot C_d \cdot C_f \cdot q_p(z_e) \cdot A_{ref}$$

$$C_s = \frac{1+7 \times I_v(z_s) \times \sqrt{B^2}}{1+7 \times I_v(z_s)} = \frac{1+7 \times I_v(z_s) \times \sqrt{1^2}}{1+7 \times I_v(z_s)} = 0.81$$

$$B^2 = 1.0 \text{ (Conservative value)}$$

$$I_v(z) = \frac{k_l}{c_0(z) \times \ln(z/z_0)} = 0.167$$

$$c_0(20) = 1.0$$

$$k_l = 1.0$$

$$z_0 = 0.05 \text{ m}$$

$z = 20$ m (Maximum column height)

$$c_d = \frac{1+2 \times k_p \times I_v(z_s) \times \sqrt{B^2 + R^2}}{1+7 \times I_v(z_s) \times \sqrt{B^2}} = 1.0$$

Force Coefficient c_f for a finite circular cylinder:

$$c_f = c_{f,0} \cdot \Psi_\lambda = 1.2$$

Steel Columns:

$$F_w = 0.81 \cdot 1.0 \cdot 1.2 \cdot 1.7 \cdot 0.45 = 0.75 \text{ kN/m}$$

Compression Ring:

Force Coefficient c_f for a Spatial Truss Structure:

$$c_f = c_{f,0} \cdot \Psi_\lambda = 2.0$$

$$F_w = 0.81 \cdot 1.0 \cdot 2.0 \cdot 1.7 \cdot 1.0 = 2.75 \text{ kN/m}$$

b) PVC - Membrane Roof

$$W = q_p(z) \cdot c_p$$

It is considered a Multibay Canopy Roof. The Net Pressure Coefficients and overall Force Coefficient are according to the Eurocode EN 1991-1-4:2005, Table 7.7 for duo pitch canopies. A reduction factor of 0.8 was considered for the upward forces and pressures in order to consider the Multibay Effect.

Roof Angle	Blockage	Overall Force Coef. Cf	Pressure Coefficients Cp			
			Zone A	Zone B	Zone C	Zone D
55	Maximum All	1.90	1.80	1.90	1.60	1.70
	Minimum 1	-1.04	-1.12	-0.64	-0.72	-1.60
"+ Values indicate a net downward wind action"						
"- Values indicate a net upward wind action"						

c) *ETFE Cushion Roof*

$$W = q_p(z) \cdot c_p$$

$$Z = 20.02 \text{ m (ETFE Roof Height)}$$

Terrain Category – II

$$q_p = C_e(Z) \cdot q_b = 2.8 \cdot 0.56 = 1.6 \text{ kN/m}^2$$

Roof Angle	Blockage	Overall Force Coef. Cf	Pressure Coefficients Cp		
			Zone A	Zone B	Zone C
0	Maximum All	0.2	0.5	1.8	1.1
	Minimum 1	-1.3	-1.5	-1.8	-2.2
"+ Values indicate a net downward wind action"					
"- Values indicate a net upward wind action"					

4.4.6 Snow Load

$S = \mu_i S_k C_e C_t$

$S_k = 0.1 \text{ kN/m}^2$

$C_e = 1.0$

$C_t = 1.0$

$\mu_1 = 0.13$

$\mu_2 = 1.60$

$S_1 = 0.13 \cdot 0.1 \cdot 1 \cdot 1 = 0.013 \text{ kN/m}^2$

$S_2 = 1.60 \cdot 0.1 \cdot 1 \cdot 1 = 0.160 \text{ kN/m}^2$

Altitude	ψ_0	ψ_1	ψ_2
$h > 1000 \text{ m}$	0.70	0.50	0.20
$h < 1000 \text{ m}$	0.50	0.20	0.00

4.4.7 Imperfections (EN 1993-1-1:2005(D) Cl. 5.3.2)

a) Compression Ring

- Precurvature
Tab. 6.2 Hollow Section -> Buckling curve “a”
Tab. 5.1 Elastic design : $e_{0,d}/L = 1/300$

Equilavalent Horizontal Forces:
 $q_i = 8 N_{ed} e_{0,d} / L^2 = 8 \times 9693 \times 1/300 \times 1/10 = 25.85 \text{ kN/m}$

$$H_i = 4 N_{ed} e_{0,d} / L = 4 \times 9693 \times 1/300 = 129 \text{ kN}$$

- Preinclination

Compression Ring horizontal inaccuracies (ovalization due to deviation angle in head plates)

Relevant buckling mode shapes for the Compression Ring are scaled to form a maximum imperfection of w_0 which is applied onto the structural steelwork as a stress-free pre deflection.

$$s_k = 48 \text{ m}$$

Structural imperfections:

$$e_0 = L / 300 = 48 \text{ m} / 300 = 160 \text{ mm}$$

$$\text{Structural part thereof } e_0 = 50\% \text{ of } e_{0,d} = 80 \text{ mm}$$

For the stability analyses imperfections for the Compression Ring are considered as:

Using this strategy a maximum tolerance or geometrical imperfection of:

$$w_{\text{geom},k} = 4 \cdot (L_{\text{sys}} \cdot \Delta \varphi \cdot 2) = 4 \times 13000 \times 0.5/1000 \times 2 = 52 \text{ mm}, \text{ may occur due to the manufacture of the CR elements } (\pm 0.5 \text{ mm} / 1000 \text{ mm} \quad (2 \text{ machined surfaces per element})).$$

$$w_0, \text{ geom.} = 1.5 \times 52 = 78$$

$$w_0, \text{ struct} = 80 \text{ mm}$$

Ersatz imperfections of $w_{0,d} = w_0, \text{ geom} + w_0, \text{ struct}$

$$w_{0,d} = 158 \text{ mm}$$

b) Diagonals

- Precurvature

Tab. 6.2 Hollow Section -> Buckling curve "a"

Tab. 5.1 Elastic design : $e_{0,d}/L = 1/300$

Equilavalent Horizontal Forces:

$$q_i = 8 N_{ed} e_{0,d} / L^2 = 8 \times 1916 \times 1/300 \times 1/10 = 5 \text{ kN/m}$$

$$H_i = 4 N_{ed} e_{0,d} / L = 4 \times 1916 \times 1/300 = 25 \text{ kN}$$

- Preinclination

$$\phi = \phi_0 \alpha_h \alpha_m$$

$$\phi = 1/200 \times 0.685 \times 0.7 = 0,0024$$

$$H_i = \phi \times N_{ed} = 0.0024 \times 1916 = 4.6 \text{ kN}$$

c) Columns

- Precurvature
- Tab. 6.2 Hollow Section -> Buckling curve "a"
- Tab. 5.1 Elastic design : $e_{0,d}/L = 1/300$
-
- Equilavalent Horizontal Forces:
- $q_i = 8 N_{ed} e_{0,d} / L^2 = 8 \times 2934 \times 1/300 \times 1/20.5 = 3,82 \text{ kN/m}$
- $H_i = 4 N_{ed} e_{0,d} / L = 4 \times 2934 \times 1/300 = 39 \text{ kN}$

- Preinclination

$$\phi = \phi_0 \alpha_h \alpha_m$$

$$\phi = 1/200 \times 0.667 \times 0.73 = 0,0024$$

$$H_i = \phi \times N_{ed} = 0.0024 \times 2934 = 7.15 \text{ kN}$$

5 Dimensioning and Detailed Design

5. Dimensioning and Detailed Design

According to the EN 1993-1-1: 2005, chapter 5.2 Global Analysis, the internal forces and moments may generally be determined using second-order analysis, taking into account the influence of the deformation of the structure.

For Uniform members in bending and axial compression in 6.3.3, EN 1993-1-1: 2005, the stability of uniform members with double symmetric cross sections for sections not susceptible to distortional deformations can be carried out using second order analysis with imperfections as given in 5.3.2, EN 1993-1-1: 2005.

5.1 Steel Structure – Upper Compression Ring

Service Limit State: Loadcase Deadload + Prestress – Bending Moments

Service Limit State: Loadcase Deadload + Prestress – Axial/Normal Force

Ultimate Limit State: Loadcase Deadload + Prestress – Bending Moments

Ultimate Limit State: Loadcase Deadload + Prestress – Axial/Normal Force

Ultimate Limit State: Von Mises Stresses : All Load Cases

In the areas where the steel stresses are higher than the admissible value of 323 MPa, the cross section will be locally reinforced.

5.11 Service – Displacements

The maximum displacement for the membrane roof is two meters downwards. The roof depth is about thirty meters. With some wind tunnel analysis the result would be more accurate.

5.12 Ponding

According to the French Code, a load of 0.60 kN/m^2 should be considered for Ponding Analysis. In this case, a 1.0 kN/m^2 was analyzed and no ponding areas were found.

8 Time Schedule

9 Future Perspectives - PVDF-Foil as Structural Element

9. Future Perspectives - PVDF-Foil as Structural Element

While the piezoelectric effect has been around for some years, it has only recently caught interest as a potential sustainable energy harvesting solution.

Among the polymeric material, PVDF exhibits higher piezo and pyroelectric properties. The combination of the mechanical properties of a plastic material with those of a piezoelectric material led to new sensors and transducers. Currently PVDF is used in a variety of applications in the electronic field. Its success in these applications is due to some advantages, such as: flexibility, low density, resistance to chemical attack, possibility of manufacturing the form of thin films and areas greater than 1m² with a reduced production cost. These features are not presented by piezoelectric ceramics materials which are hard and brittle. Piezoelectric polymer materials can generate higher voltage/power than ceramic based piezoelectric materials and it was proved that producing energy from renewable sources such as rain drops and wind is possible by using piezoelectric polymer materials.

Piezoelectric effect is defined as the electric charge generated in certain materials by mechanical stresses. Piezoelectricity has gained significant importance in research and development for extracting energy from the environment.

Pyroelectric effect is defined as the electric charge generated in certain materials as response to temperature variations.

PVDF can crystallize in at least four distinct forms, called phases α , β , γ and δ . The β phase (polar) is of greater interest for the present, which has piezo and pyroelectric properties. However phase α (nonpolar) is more easily obtained by the industry. There are several mechanisms that transform α phase in β phase, the most common is by mechanical deformation of the α phase in temperatures below 80 degrees, resulting in polar material with the total dipole moment of the order of $6.9 \times 10^{-30} \text{C.m}$. To obtain high levels of piezoelectric activity, the beta phase polymer is exposed to very high electric fields to align the crystallites relative to the poling field.

Figure 15 - PVDF-based Pyroelectric Energy Harvester - Plot of (a) Environment Temperature at Saudi Arabia and Respective (b) Generated Voltage and (c) Energy (Source: <http://www.cscanada.net/>)

The potential for energy harvesting through Pyroelectric effect was studied by using piezoelectric materials such as PVDF. Peak power density was experimentally determined to be $0.12 \mu\text{W}/\text{cm}^2$ for PVDF. It can be estimated that thin films with larger area and higher pyroelectric coefficient can generate nearly three orders of magnitude improved peak power density for PVDF samples. 5. Piézotech's PVDF piezoelectric films properties ⁽¹⁾

Characteristics	Bioriented Films
Nominal thickness (µm)	9 to 50
Thickness regularity (%)	± 10
Poled width of roll (cm)	25
Length of roll (m)	Variable: 5 to > 200
Piezoelectric properties (non metallized films)	Bioriented Films
$d_T = d_{33}^*$, (10^{-12} C/N)	13 to 22
d_{31}^* (10^{-12} C/N)	6 to 10
d_{32}^* (10^{-12} C/N)	6 to 10
Regularity of piezoelectric coefficients, (%)	± 10
Variation of the coefficients at metallization, (%)	0 to 15 ⁽²⁾
Relative dielectric constant ϵ/ϵ_0 ($\epsilon_0 = 8.85 \cdot 10^{-12}$ F/m), between 50 Hz and 100kHz, $T^\circ = 25^\circ\text{C}$ to 90°C	10 to 12
g_{33}^* (V.m/N)	0.14 to 0.22
Pyroelectric coefficient, ρ (10^{-6} C/m ² .K)	24 to 26
Transverse resistivity (Ω.cm)	$5 \cdot 10^{14}$
Electromechanic coupling factor K_T (%)	10 to 15
Mechanical properties	Bioriented Films
Tensile strength (MPa):	
- Machine direction:	60 – 160
- Transverse:	60 – 160
Elongation at break (%):	
- Machine direction:	40 – 140
- Transverse:	40 – 140
Modulus of elasticity (MPa):	
- Machine direction:	1600 – 2200
- Transverse:	1600 – 2200
Shrinkage after 1 hour, Oven at 160°C (%):	
- Machine direction:	2 – 15
- Transverse:	1 – 13
Shrinkage after 100 hour, Oven at 80°C (%):	
- Machine direction:	2 – 3
- Transverse:	N.A.

⁽¹⁾: This range is experimental and susceptible to changes.

⁽²⁾: Excessive heating may destroy piezoelectricity. It is advised not to heat above 90°C for more than 1 hour.

Figure 16 – PVDF Piezoelectric Film Properties (source: <http://www.piezotech.fr/>)

Advantages of PVDF Film:

- Excellent chemical resistance
- Stable to UV & effects of weather
- Low NBS smoke generation & superior LOI
- Excellent Transmittance of Solar Energy & Excellent Dielectric Strength
- Excellent Physical & Mechanical Properties
- PVDF is FDA & FM 4910 compliant
- Thicknesses are displayed in inches. (see metric conversion): .001" = 25.3 micron, .003" = 76.2 micron, .005" = 127 micron, .010" = 254 micron, .020" = 508 micron

Ajedium™ Films -- Solef® PVDF 9009

polyvinylidene fluoride

Solef® 9009 PVDF homopolymer is a semi-crystalline fluoropolymer. Solef® film is chemically inert to most acids, aliphatic and aromatic organic compounds, chlorinated solvents and alcohols.

Solef® PVDF film has a very high purity, abrasion resistance comparable to that of polyamides and relatively low coefficient of friction. These films can be used in a wide range of temperatures and have excellent intrinsic fire resistance.

Solef® PVDF films have demonstrated excellent weathering properties and are extremely resistant to UV radiation and common industrial and environmental pollutants.

Solef® PVDF films can be used in a wide range of applications, including: release films, filters, chemical resistance lining, outdoor UV resistant needs as well as electric and electronic applications.

Standard Thicknesses and Widths

- Widths are available from 22" (559 mm) to 56" (1422 mm).

- Products with widths <22 inches or >56 inches are available upon request.
- Tolerances for widths are +/- 4mm.
- For PVDF film, the standard thicknesses are 25 microns (1 mil) to 1016 microns (40 mil), with a tolerance of +/- 10%.

Surface Finishes

- Standard surface finish is P/M (polished / matte).
- Custom finishes of P/P (polished / polished) and M/M (matte / matte) are available.

Packaging

- Film is supplied in a roll form of high quality, cardboard core of 3" (76mm) or 6" (152mm).
- PVC cores are available upon request in 3" and 6" sizes.

Labeling

- Products are labeled to comply with national and international standards.
- Labels include product grade, unique batch number, roll length, roll width, product thickness, and net weight.

General

Material Status	• Commercial: Active	
Availability	• Asia Pacific	• Latin America
	• Europe	• North America
Features	• Homopolymer	

Physical	Typical Value	Unit	Test method
Specific Gravity	1.75 to 1.80		ASTM D792
Water Absorption (23°C, 24 hr)	< 0.040	%	ASTM D570

Mechanical	Typical Value	Unit	Test method
Coefficient of Friction			ASTM D1894
vs. Itself - Dynamic	0.15 to 0.35		
vs. Itself - Static	0.20 to 0.40		
Taber Abrasion Resistance			ASTM D4060
1000 Cycles, 1000 g, CS-10 Wheel	5.00 to 10.0	mg	

Films	Typical Value	Unit	Test method
Film Thickness - Tested	25	µm	
Secant Modulus			ASTM D882
MD	2000	MPa	
TD	2100	MPa	

Revised: 7/4/2014

Ajedium™ Films -- Solef® PVDF 9009

polyvinylidene fluoride

Films	Typical Value	Unit	Test method
Tensile Strength			ASTM D882
MD : Yield	55.0	MPa	
TD : Yield	56.0	MPa	
MD : Break	57.0	MPa	
TD : Break	54.0	MPa	
Tensile Elongation			ASTM D882
MD : Yield	6.0	%	
TD : Yield	6.2	%	
MD : Break	200	%	
TD : Break	250	%	
Free Shrinkage (130°C)	0.70	%	ASTM D2732
Area Factor	108	ft²/lb/mil	

Thermal	Typical Value	Unit	Test method
Glass Transition Temperature	-40.0	°C	ASTM D4065
Melting Temperature	162 to 168	°C	ASTM D3418
Peak Crystallization Temperature (DSC)	133 to 140	°C	ASTM D3418
CLTE - Flow	0.00014	cm/cm/°C	ASTM D696
Specific Heat (100°C)	1600	J/kg°C	ASTM C351
Thermal Conductivity	0.20	W/m/K	ASTM C177

Electrical	Typical Value	Unit	Test method
Surface Resistivity	> 1.0E+14	ohm	ASTM D257
Volume Resistivity	> 1.0E+14	ohm-cm	ASTM D257
Dielectric Strength (23°C, 1.00 mm)	20 to 25	kV/mm	ASTM D149
Dielectric Constant	7.50		ASTM D150

Flammability	Typical Value	Unit	Test method
Oxygen Index (3.00 mm)	44	%	ASTM D2863

Notes

Typical properties: these are not to be construed as specifications.

Figure 17 – PVDF Film Properties – Copyright Solef

The possible applications for PVDF-Foil as Structural Element in the Building Industry are the following:

a) Active Acoustic Control

Passive noise control aims to suppress the sound by absorbing the sound waves. “Modifying and canceling sound field by electro-acoustical approaches is called active noise control” (source: <http://en.wikibooks.org/>). The actuators, as an acoustic source, produce completely out of phase signals to eliminate the disturbances.

Figure 16 – Passive and Active Noise Control (source: <http://en.wikibooks.org/>)

It is known that Etfе cushions offer poor acoustic insulation. One solution to improve this situation could be to introduce pvdf film as a middle layer in a cushion and use it as an active acoustic control panel to reduce residual noise.

Figure 17 – Film speaker is made from piezoelectric film called PVDF (source: <http://www.telovation.com/articles/stereo-film-speakers.html>)

“Developed by Korean electronics manufacturer FILS, this innovative and transparent material is actually a stereo speaker system. It is thin and flexible and has a wide frequency and dynamic band, low impedance, high induced electricity and mechanism, low density and high sensitivity.” (Source: <http://www.telovation.com/articles/stereo-film-speakers.html>)

b) Piezoelectric PVDF Cushions for Façades and Roofs.

Etfe Cushions have been constructed around the world in buildings in the last years. An alternative to ETFE could be the use of PVDF. The mechanical characteristics are identical for both materials.

	Thickness	Tensile Strength Yield	Tensile Strength Break	Tensile Elongation Yield	Tensile Elongation Break	Secant Modulus	Flexural Modulus	Flammability Rating	Melt Point
ETFE Film (Dupont)	0.050 mm	-	41 MPa	-	300%	-	830 MPa	V-0	260-280 C
PVDF Film (Solef)	0.025 mm	54 MPa	54 MPa	6.2%	250%	2100 MPa	-	V-0	160 C

Temperature variation and wind loads could generate energy through piezoelectric effect on the PVDF Cushion.

PVDF has an excellent chemical resistance and is stable to UV and weather effects. The only thing that is discussable is the low Melting Point of PVDF.

Further research to the use of PVDF film in the building industry should be done.

c) Renewable Energy – Solar Updraft Tower roof collector

PVDF single layers could be used for the Solar Updraft tower roof collector. The collector is used to warm up air (greenhouse effect), which is then “sucked” by the tower (chimney effect) generating energy from wind turbines. Instead of using a “passive” material just with the function of creating a greenhouse, there is the possibility of using a material like piezoelectric PVDF film that produces also energy with temperature variations and wind loads.

Figure 18 –Solar Updraft Tower (left) and ETFE film for solar updraft tower in Manzanara, Spain (right) (Copyright: Schlaich Bergermann und Partner)

The Peak Power density was experimentally determined to be $0.12 \mu\text{W}/\text{cm}^2$ for PVDF. The collector area for a 100 MW Solar Updraft Tower is around 14505151 m^2 . Thus, the peak power generated by the collector is 17.4 MW!

There is the chance of building a 100 MW solar updraft tower by phases. First a part of the roof collector, which can start generating energy by the piezoelectric effect due to temperature and wind. Then, on a second phase the whole roof and the energy generated can start subsidizing the chimney/tower project. On the last phase, the tower can be built.

Pvdf film has a higher light transmittance than ETFE film. Thus, the greenhouse effect is guaranteed under the roof collector.

Figure 19 –Transmittance of PVDF and ETFE film (Source: <http://www.aitechnology.com/products/solar/transparent-pvdf-encapsulating-front-sheet/>)

The boundaries of lightweight structures and materials can be overcome once more in the near future with the use of PVDF film.
