## Referat (English Version)

**Introduction and objective:** Diabetes with its complications and consecutive deaths has already become a global health burden and its prevalence will further increase during the coming years. Low- and middle income countries (LMIC) are expected to experience the highest increase over the years causing premature mortality. Therefore, it is necessary to conduct baseline research on interventions to treat patients with diabetes to approach the specific African context and regional circumstances with the aim to implement adequate diabetes management strategies. The objective of this review was, to collect the best locally generated evidence on diabetes interventions, identify knowledge gaps and underexplored research areas.

**Methods:** The protocol was prospectively registered on PROSPERO (CRD42019122785) and follows the recommendations of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) and the methods described in the Cochrane Handbook for systematic reviews of interventions. Three electronic databases (MEDLINE Ovid, CENTRAL, CINAHL) and register of ongoing and completed studies (International Clinical Trials Registry Platform) were searched. Main characteristics of all eligible randomized controlled trials (RCTs) were extracted and narratively described, presented in form of tables and their main results on HbA1c were visualized as forest plots. The risk of bias was assessed.

**Results.** A total of 50 RCTs in 56 publications were identified, in which a wide variety of interventions were carried out in different parts of Africa. Interventions addressed non-pharmacological strategies on education, lifestyle modification (Nutrition and activity) and substance related therapies. Most were conducted in urban regions. Only nine studies were conducted in a primary care setting.

**Conclusions:** This systematic review shows that even though diabetes is a critical health problem in different regions and settings in Africa, the number of RCTs conducted on the African continent is still low. Available RCTs might not be representative for all Africans, as they are focusing only on a few countries and urban settings. The empowerment of the primary care doctors and nurses is crucial to establish a continent wide diabetes care system. The benefits and challenges of the implementation of a digital health system should be proved. Therefore, feasible RCTs adapted to local resources need to be conducted in order to form local guidelines and recommendations continent-wide.

## Referat (Deutsche Version)

Einleitung und Zielsetzung: Diabetes, seine Komplikationen und die damit verbundenen Todesfälle sind bereits zu einer globalen Gesundheitsbelastung geworden. Die Prävalenz wird auch in den nächsten Jahren zunehmen, besonders in Ländern mit niedrigem und mittlerem Einkommen. Daher ist es notwendig, dass klinische Forschung angepasst an den spezifischen afrikanischen Kontext, durchgeführt wird, um angemessene Strategien für das Diabetesmanagement zu entwickeln. Das Hauptziel dieser systematischen Übersichtsarbeit, ist die Zusammenfassung der lokal durchgeführten, bereits vorhandenen randomisierten klinischen Studien (RCTs), um Wissenslücken und unerforschte Forschungsbereiche zu identifizieren.

Methoden: Das Protokoll wurde im Voraus in der PROSPERO-Datenbank registriert (CRD42019122785) und folgt den, in den PRISMA Statement und dem Cochrane-Handbuch empfohlenen Methoden. Eine systematische Suche in drei elektronischen Datenbanken (MEDLINE Ovid, CENTRAL, CINAHL) und im Register laufender und abgeschlossener Studien (International Clinical Trials Registry Platform) wurde durchgeführt. Die Hauptmerkmale aller in Frage kommenden RCTs wurden extrahiert und narrativ beschrieben, in Form von Tabellen dargestellt und deren Ergebnisse hinsichtlich des HbA1c als Forest Plots visualisiert. Das Risiko einer Verzerrung der Ergebnisse wurde bewertet.

Ergebnisse. Insgesamt 50 Studien (56 Publikationen) mit unterschiedlichen Interventionen aus verschiedenen Teilen Afrikas wurden identifiziert. Die Interventionen bezogen sich auf nicht-pharmakologische Strategien zur Aufklärung, Lebensstiländerung (Ernährung und Aktivität) und substanzbezogene Therapien. Die meisten wurden in städtischen Regionen durchgeführt. Nur neun Studien untersuchten Interventionen in der Primärversorgung.

Folgerungen: Diese systematische Übersicht zeigt, dass die Zahl der auf dem afrikanischen Kontinent durchgeführten RCTs insgesamt niedrig ist. Die verfügbaren Studien sind möglicherweise nicht repräsentativ für alle Afrikaner, da sie sich nur auf einige wenige Länder und überwiegend städtische Gebiete konzentrieren. Die Primärversorgung sollte durch eine verstärkte Zusammenarbeit von ärztlichem und nicht ärztlichem Personal intensiviert werden. Außerdem sollten in Zeiten der zunehmenden Digitalisierung der vermehrte Ausbau eines digitalen Gesundheitssystems eruiert werden.

## 1 Introduction

Within the last years, the prevalence of diabetes has increased worldwide, becoming a serious global health burden [1]. According to the World Health Organization (WHO) the prevalence of diabetes, its complications and consecutive deaths will further increase during the next years, becoming the seventh global leading cause of death by 2030 [2–5].

For a long time, diabetes was considered to be a disease of affluence [1]. Today most people suffering from diabetes live in the low- and middle income countries (LMIC) where the highest increase of diabetes cases is expected over the next years [2]. For these countries predictions are of high relevance, as these countries suffer from a double burden due to the epidemiological transition from the communicable (infectious) to the non-communicable diseases (NCDs) with a relevant shift in causes of disability and death [3, 6, 7]. Focussing on reducing the burden of high premature mortality due to NCDs like diabetes through prevention and treatment has been designated as a target within the United Nations 2030 Agenda (Target 3.4) [8]. According to the International Diabetes Federation (IDF), an estimated 19.4 million adults between the 20 - 79 years of age were suffering from diabetes in the African region in 2019. The regional reported prevalence in Africa is 3.9 % with a high variation between the different countries [9]. This number is estimated to increase to about 47 million by 2045. Africa has the highest amount of undiagnosed diabetes cases among all IDF regions. The IDF estimates that approximately 60 % of the adults living with diabetes are unaware of it. Egypt is belonging to the Middle East and Northern Africa IDF region and is ranked at the ninth place of the top ten worldwide countries with diabetes in adults between 20-79 years [9]. In this region an 96 % increase of diabetes cases is expected by 2045 [9].

The increasing prevalence and premature mortality due to diabetes leads to substantial financial costs to households and governments [5, 10].

Diabetes is a non-communicable chronic disease affecting the glucose metabolism. The pathomechanism differs between the different diabetes entities. However, what they all have in common is leading to a high blood glucose level, which eventually damages organs like the heart, the blood vessels, the kidneys, the nervous system, the eyes and the teeth and are associated with an increased risk of infections [11, 12].

All interventions on diabetes aim for achieving glycemic control since longer lasting elevated blood glucose levels will contribute to diabetes related complications. The interventions include a regular evaluation of risk factors, detection of early stages of diseases, a step therapy with a combination of non-pharmacological and

---

pharmacological treatment, a long term follow up with regular monitoring and promotion to improve treatment adherence [13]. For both, the prevention and the treatment of type 2 diabetes (DM2) and gestational diabetes mellitus (GDM), the first step will be a modification of the lifestyle including frequent activity and nutritional optimization in order to regulate body weight [14, 15]. If the target HbA1c/blood glucose level cannot be achieved, the next step then will be a substance related therapy with the first line of treatment being metformin for DM2 and Insulin for GDM [16, 17].

Prediabetic conditions, which are strongly associated to a low physical activity and elevated body weight, are characterised by impaired glucose tolerance and impaired fasting glucose and can lead to DM2. Therefore, especially the non-pharmacological strategies such as lifestyle modification can prevent developing overt diabetes [18].

The underlying pathomechanism of diabetes mellitus type 1 (DM1) differs from the other diabetes entities. People suffering from DM1 have an absolute insulin deficiency resulting in the necessity of substituting insulin [11].

Secondary and tertiary prevention of all diabetes entities include at least screening and treatment for retinopathy, elevated blood cholesterol levels, elevated blood pressure, screening for early signs of diabetes related kidney disease and foot care [4].

It is necessary to conduct baseline research on diabetes to approach the specific African context and regional circumstances with the aim to implement adequate diabetes management strategies. Interventions have to be adjusted to the local context including the environmental, cultural and social settings (e.g. relatively young age of the patients, co-infections with for example malaria, tuberculosis etc., distance to health care, traditional beliefs, decision making in the families and socioeconomic status) as well as the huge genetic diversity on the African continent [19].

There is a demand for well-informed solutions to formulate effective health agendas for prevention, availability and affordability of treatment options. This emphasizes the need of research on interventions to prevent, diagnose and treat diabetes in appropriate settings, organized around the needs and expectations of people in African context.

---

## **2 Objective**

This study aims to collect the best available evidence on benefits and harms of prevention, diagnostic and therapeutic interventions on diabetes in the African context with the purpose of helping to address the existing knowledge gaps and unexplored research areas and to identify resources of application of evidence-based interventions. This may support the formulation of strategies to strengthen clinical and preventive capacities of current healthcare systems in African countries.

---

### **3 Methods**

This systematic review follows the recommendations of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) [20] and the methods described in the Cochrane Handbook for Systematic Reviews of Interventions [21]. The protocol has been registered in the PROSPERO International Prospective Register of systematic reviews and published (CRD42019122785).

#### **3.1 Inclusion criteria and exclusion criteria**

Studies initiated and conducted in African countries investigating the efficacy of interventions for screening, diagnosis and treatment of patients with diabetes illnesses (DM1, DM2, GDM and prediabetes) on mortality, quality of life, hospital admission, intensification rates of therapy, treatment adherence, adverse effects, complications, costs and glycemic control were identified. Included were full-text publications on individual RCTs, cluster-RCTs and randomized cross-over trials according to the Consolidated Standards of Reporting Trials (CONSORT) [22] or Standard Protocol Items: Recommendations for Interventional Trials (SPIRIT) statement [23]. International multicenter studies with less than 50 % of sites in African countries and non-English published studies were excluded (Table 1).

**Table 1: Inclusion and exclusion criteria**

Design and setting	RCTs initiated and conducted in African countries, at least 50 % African countries
Population	African patients in African countries in secondary or tertiary prevention with a clinical diagnosis of diabetes <ul style="list-style-type: none"><li>– DM2</li><li>– DM1</li><li>– GDM</li><li>– Prediabetes</li></ul>
Interventions	All interventions to screen, diagnose and treat patients with diabetes Exclusion of trials if diabetes is only a possible side effect of treatment
Comparison	<ul style="list-style-type: none"><li>– Placebo</li><li>– Standard care</li><li>– Another intervention</li><li>– Same intervention with a different dose or timing</li></ul>
Outcome	Primary: all-cause mortality, quality of life Secondary: hospital admission, intensification rates of therapy, treatment adherence, adverse effects, complications, costs and glycaemic control (HbA1c, fasting plasma glucose, random plasma/blood glucose, two hour plasma/blood glucose during oral glucose tolerance test, insulin resistance, fasting glucose insulin ratio) at longest follow-up
Publications	Full-text publications according to CONSORT or SPIRIT Exclusions of protocol or design papers, conference proceedings or papers where full-text publications were not available

CONSORT: Consolidated Standards of Reporting Trials; DM: Diabetes mellitus; HbA1c: hemoglobin A1c; RCT: randomized controlled trial; SPIRIT: Standard Protocol Items: Recommendations for Interventional Trials

### 3.2 Search strategy

A systematic search in three electronic databases (MEDLINE Ovid, CENTRAL, CINAHL) was performed in 2019. And a search in registers of ongoing and completed studies (International Clinical Trials Registry Platform (ICTRP)) without any time restriction was added in 2020. The search strategy is available in the supplementary material. Search strings included MESH-terms and terms on diabetes, Africa and a list of all 54 African countries and terms related to RCTs.

### 3.3 Study selection and data extraction.

For the first step, titles and abstracts were screened independently by my supervisor, Susanne Unverzagt, hereinafter referred to as SU and me, on the basis of the inclusion criteria (Table 1). The full texts of those potentially eligible papers were obtained and

---

further assessed for final inclusion. Disagreements were resolved by discussion including a third investigator, Thomas Frese (TF), until consensus was obtained.

In a second step, the reported pre-defined information on:

- Author, study name and design
- Country, environmental settings (urban vs. rural) and health care settings (primary vs. other settings (secondary or tertiary), period for inclusion
- Study population (including inclusion and exclusion criteria, sample size and baseline characteristics on age, gender, type and length of diabetes, diagnostic criteria, BMI, co-morbidities)
- Intervention vs. control group and number of randomized participants per group
- Outcome parameters (primary, secondary, non-specified) and
- Results on pre-planned outcomes within longest follow up period with intervention effects, 95 % confidence intervals (CI) and p-values

of all included studies was extracted by me. All extracted information was checked by SU.

The study names consist of the surname of the first author and the year of the first full-text publication of the results.

The study selection process was described in a flow chart (Figure 1) according to the PRISMA statement [20].

### **3.4 Quality assessment and risk of bias**

In a third step, the risk of bias on the basis of the Cochrane risk of bias tool along seven specific categories (sequence generation, allocation concealment, blinding of participants, personnel and outcome assessors, incomplete outcome data, selective outcome reporting and other sources of bias) was described and judged as 'low', 'high' or 'unclear' due to insufficient information [21]. A summary table and a diagram illustrate these findings. The critical appraisal of the included studies was checked by SU. Discrepancies were resolved by discussion.

Judgements on blinding and incomplete outcome data were based on the primary outcome of included studies. Selective outcome reporting was defined as low, when the study protocol was available and high when any result of pre-planned outcomes was missing. Incomplete outcome data was judged as high when more than 10 % of randomized participants dropped out from analyses. Other sources of bias judged as high risk of bias include missing reporting of sample size calculation, no definition of a primary endpoint and missing reporting or relevant differences of baseline values between intervention and control group [21].

---

### **3.5 Effect sizes**

The results of all outcomes were narratively described. For all RCTs in which most participants suffered from DM2, intervention effects for HbA1c at the longest follow-up period were calculated and visualized in forest plots using the Cochrane Revman Manager [24]. Negative mean differences (MDs) describe lower HbA1c in the intervention group. Statistical significant results on HbA1c with MDs over 0.25 % for HbA1c were named clinically relevant [25].

---

## 4 Results

Having used the mentioned criteria to identify potentially relevant articles, a total of 1928 records were identified of which the majority was found in MEDLINE (Ovid; November 2018, n = 1470). In CENTRAL, another 439 records were identified (January, 2019). Additional 871 studies in Clinical Trials registry Platform were checked and searched for full-text publications (October 2019). In total, 191 potentially eligible publications were evaluated as full-texts to be of relevance. In January 2020, a search in CINAHL (n = 19) was added without identifying new potentially eligible studies. A total of 50 eligible studies in 56 publications were included in this review (Figure 1). A list of the included is documented in the supplementary material.

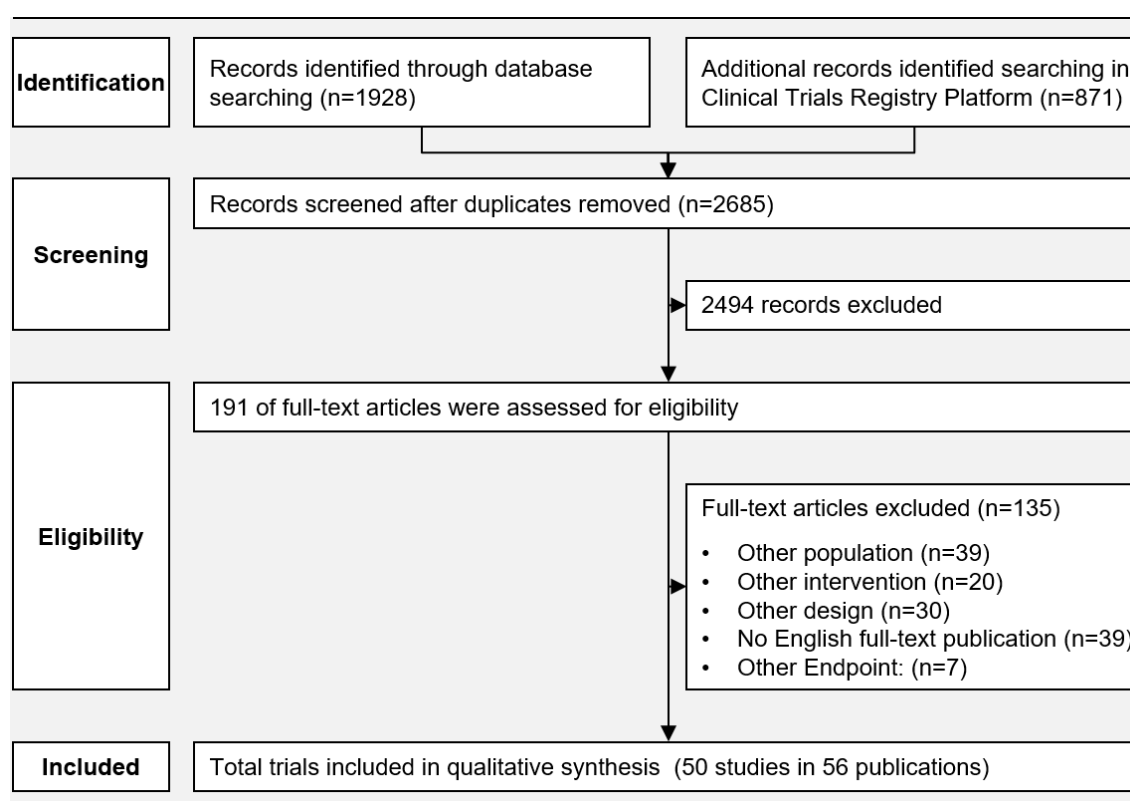

Figure 1: PRISMA flow chart demonstrating the flow of studies in this review

### 4.1 Description of included studies

#### 4.1.1 Setting

##### 4.1.1.1 Geographical aspects

In total RCTs from 15 countries from all 5 geographical regions were included: Northern Africa (23 RCTs from 4 countries), Western Africa (10 RCTs from 3 countries), Eastern Africa (4 RCTs from 5 countries), Central Africa (3 RCTs from 2 countries) and Southern Africa (13 RCTs only from South Africa). Another two RCTs

---

(Malek 2015 and Chraibi 2017) were conducted in more than one country and were partially conducted in non-African countries [26, 27]. Egypt was the number one country in terms of overall number of publications (21 RCTs), followed by South Africa (13 RCTs) and Nigeria (6 RCTs) (Table 2 available in the appendix, Figure 2 and 3). Since some studies had been conducted in more than one country and the separate publications of the included RCTs have been counted individually, a deviation from the number of included studies and the number of studies in Figure 2 resulted.

Figure 2: Geographical regions, countries and type of diabetes based on the results of this RCT.

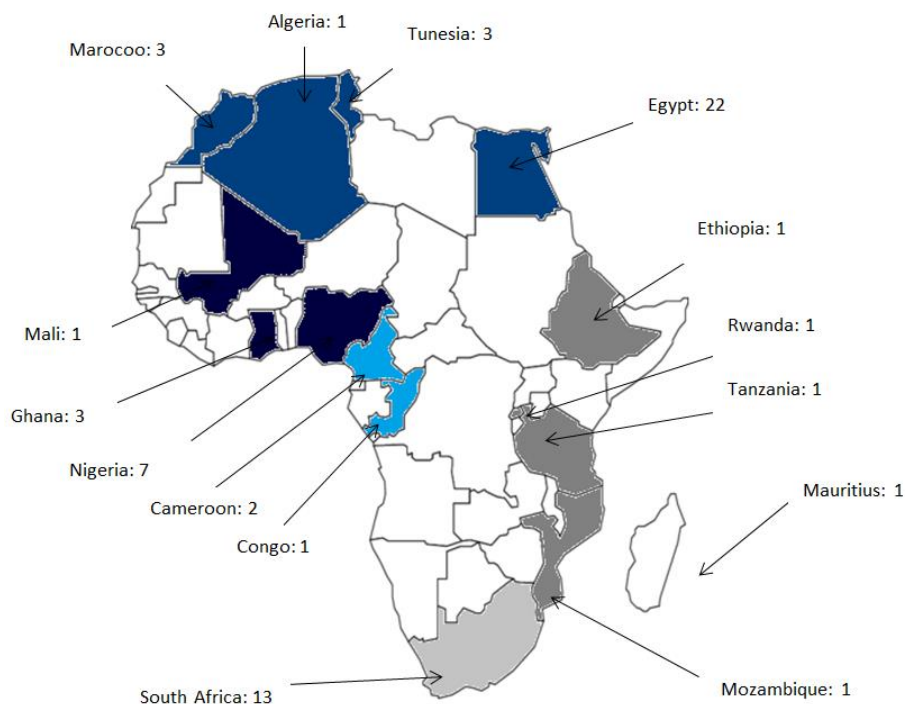

Figure 3: Overview of the geographical distribution of the included studies

Figure adopted from <http://www.supercoloring.com/de/ausmalbilder/karte-von-afrika> and edited in Microsoft Paint.

---

#### **4.1.1.2 Temporal aspects**

Considering that the systematic search was carried out without any time restriction, it is interesting, that our oldest eligible RCT (Anderson 2001) was published in 2001 [28]. More than 75 % were published within the last 5 years and 3 of them had been published in 2019 (Table 2).

#### **4.1.1.3 Environmental aspects**

Over 75 % (38/50) of the RCTs were carried out in an urban area, only 6 % (3/50) of the RCTs were conducted in a rural area and for 18 % (9/50) of the RCTs, it was mixed or remained unclear (Table 2). The majority of the RCTs took place in secondary and tertiary health care centres. Only 18 % (9/50) of the RCTs were conducted in a primary care setting.

#### **4.1.1.4 Design**

In total 41 parallel-group RCTs with random assignment of participants, six cluster-RCTs where each participant receives interventions in a random sequence and six cross-over RCTs where pre-existing groups of participants were randomly assigned to different interventions, were included.

The six cluster RCTs [29–37] can be described as follows. Fairall 2016 randomised public sector primary care clinics [33]. Labhard 2011 evaluated treatment adherence of patients which received free treatment for one month, if they regularly attended follow up visits or received reminder letters, when they missed on appointment vs. no additional intervention in the control group in 33 nurse-led facilities in rural health districts in Cameroon [29]. Mash 2014 evaluated group education programs in 34 public sector community health centres [30, 31]. Steyn 2013 randomized implementing structured clinical guidelines vs. usual care in 18 community health centres [32]. The last two cluster RCTs evaluated different screening strategies: Utz 2018 for GDM in 20 health care centers [34] and Webb 2015 for diabetes related complications in 12 primary health care clinics [35–37].

All of the three cross-over RCTs evaluated nutritional strategies [38–40]. Abdulrhman 2013 evaluated metabolic effects of honey consumption on patients with DM1 over 12 weeks [38]. Krawinkel 2018 included individuals with prediabetes who received bitter gourd supplementation for 8 weeks followed by placebo for another 8 weeks or starting with placebo first and then changed after 8 weeks to bitter gourd supplementation with a wash out time of 4 weeks in between [39]. Van der Hoogt 2017 evaluated different composition of meals (low vs. high protein and fat content meals) in patients with DM1

---

in both cases blood glucose was measured after 10 h post-meal. There had to be at least one day and maximum one month between meals [40].

#### **4.1.2 Participants**

In total 9331 patients were included with less than 100 patients in 55 % of the RCTs (Table 2). Overall 65 % of the study participants were women; 6 RCTs included only female [34, 41–45] and one RCT, Yan 2014, included only male participants [46]. Mean age differs between 10.4 years in van de Hoogt 2017 [40] to 19.9 years in Mohamad 2019 [47] for patients with DM1, 24.2 years in El-Shamy 2018 [41] to 27.6 years in Utz 2018 [34] for pregnant women with GDM and 39.4 years in Maharaj 2016 [48] to 59.8 years in Labhard 2011 [29] for patients with DM2. The mean age of the prediabetic participants in Krawinkel 2018 was  $47.5 \pm 8.7$  years [39].

The majority of RCTs included patients suffering from DM2 only (26 RCTs) [26–31, 46, 48–70] followed by RCTs with DM1 patients (seven RCTs [38, 40, 47, 71–74]). Only 4 RCTs were on GDM only [34, 41–43] and one on prediabetes [39]. Two RCTs, Beyuo 2015 and Ibrahim 2014, included pregnant patients with either pre-existing diabetes or GDM [44, 45]. Another 10 RCTs [32, 33, 35–37, 75–81] included patients with more than one diabetes category or did not provide sufficient information for further categorization (Figure 2). The included RCTs present a wide variety of patients in different stadiums of DM and general conditions. Including rather healthy pregnant young women suffering from GDM and children with DM1 without any other comorbidities, to patients with severe diabetes related complications. Mean duration of diabetes (reported in 26 RCTs) ranged from 2.5 years in Maharaj 2016, a RCT including patients with DM2 for rebound exercise as intervention [48] until 16.7 years in Netleki 2015, including patients with diabetic ulcers as a typical diabetes related complication [63].

Mean baseline HbA1c (reported in 46 RCTs) ranged from 6.75 % in Rashad 2017 [64] to 11.1 % in Muchiri 2015 [62] for patients with DM2. Body mass Index (BMI) as a relevant risk factor for GDM and DM2 [14] (reported in 31 RCTs) varied for patients with DM2 between mean values of 22.4 kg/m<sup>2</sup> in Fayahun 2018 [60] and 40.8 kg/m<sup>2</sup> in Distiller 2014 [55]. A total of 84 % of RCTs reported mean BMI values over 25 kg/m<sup>2</sup> and 48 % even over 30 kg/m<sup>2</sup>.

#### **4.1.3 Interventions**

Most RCTs investigated the efficacy of non-pharmacological interventions (31 RCTs) including educational strategies (17 RCTs), life-style modifications (11 RCTs) and

---

further non-drug based strategies (three RCTs). The other ones investigated substance-related therapies (19 RCTs) as an intervention.

#### **4.1.4 Non-pharmacological strategies**

##### **4.1.4.1 Educational strategies**

A total of 15 RCTs [29–31, 33, 37, 49–52, 54, 59, 61, 62, 66–68, 75, 77] with in total 5962 participants and follow-up periods between 2 months in Takenga 2014 [67] and 24 months in Webb 2015 [37] examined training or educational measures for patients (Table 2). Topics included diabetes, treatment of diabetes including life style modification measures, dietary recommendation, drug based therapy and diabetes-related complications. The training sessions were provided on the basis of group based educational sessions or individual treatment plans by nursing staff or pharmacists. They were complemented by lectures, discussion services, brochures, newsletters, computer programs, information and communication technologies and telemonitoring systems and strategies to support self-management. Three of these RCTS were nurse-led interventions in which nurses played the central role in patient education and care [29, 33, 61].

Another two cluster-RCTs and two publications resulting from Webb 2015 [32, 34–37] with in total 1270 participants and follow-up periods between some months until delivery in Utz 2018 [34] and 24 months in Webb 2015 [35, 36] focused on educational strategies to improve adherence. Of those, two focused on diagnostic strategies. Webb 2015 aimed to determine the efficacy of a mobile based intervention on glycaemic control and diabetes related complication screening in a primary care setting in South Africa, however after one year no difference in HbA1c and no change in taken or not taken actions between both groups could be shown [35, 37]. The screening for diabetic complication was significant increasing in both arms. From this cluster randomized trial another publication resulted especially on retinopathy, maculopathy and visual loss being a typical complication of diabetes [36]. Utz 2018 was on diagnostic and initial management of GDM conducted in a primary health care setting without stating a difference of glycaemic control [34]. Steyn 2013 was also carried out in a primary care setting evaluating the effects of structured diabetes and hypertension records with no benefit for the interventional group after one year [32].

##### **4.1.4.2 Life-style modification**

A total of seven RCTs [42, 46, 48, 60, 70, 74, 76] with 583 participants and follow-up periods between two months in Asuako 2017 [76] and six months in Salem 2010 [74]

---

included interventions evaluating the efficacy of strategies to enhance physical activity. The training lessons included both, aerobic and anaerobic exercises but the majority of the interventions were on aerobic exercise. The type of exercise differed between walking in Fayahun 2018 and van Rooijen 2004 [60, 70], training sessions on treadmill in Asuako 2017, Embaby 2016 and Yan 2014 [42, 46, 76], a combination of treadmill, weightlifting, flexibility and neuromuscular exercises in Salem 2010 [74] and rebound exercise in Malek 2015 [26]. The lesson frequency offered per week was between one time, three times and daily. Typically, one lesson consisted of 45 minutes. Walking, on treadmill or without was the main form of exercise.

Another four RCTs [38–40, 47] with 168 participants and follow-up periods between two months in Krawinkel 2018 [39] and four months in Mohamad 2009 [47] evaluated the efficacy of nutritional strategies including special nutritional effects of diverse foods (e.g. camel milk in Mohamad 2009 [47], honey in Abdulrhman 2013 [38], bitter gourd in Krawinkel 2018 [39]) and different composition of meals (low vs. high protein and fat content meals) in van der Hoogt 2017 [40].

#### **4.1.4.3 Further strategies**

This category includes three RCTs on non-drug related measures: [41, 63, 69] with 71 participants and follow-up periods of three months, mostly on treating diabetic complications such as diabetic foot disease (phototherapy in Netleki 2015 [63] and periodontitis (ultrasonic scaling in Tsobgny-Tsague 2018 [69]), which are not substance related. El-Shamy 2018 evaluated the effects of acupressure on patients with gestational diabetes [41].

#### **4.1.5 Substance-related strategies**

In total 19 RCTs [26–28, 43–45, 53, 55–58, 64, 65, 71–73, 79–81] belong to this group with 1774 participants and follow-up periods between one month in Elbarbary 2016 [72] and 12.5 months in Malek 2015 [26]. These substances included the most common used in diabetes therapy such as Metformin only in Ibrahim 2014 [45], Metformin combined with Insulin in Ashoush 2016, Beyuo 2015 and Distiller 2014 [43, 44, 55]) and Insulin only in Chraibi 2017, Elbarbary 2016 and Malek 2015 [26, 27, 72]. 12 RCTs evaluated other substances [28, 53, 56–58, 64, 65, 78, 79, 81], namely various systematic effecting substances (Ketotifen in El-Hagggar 2015 [56], L-Carnitine+glimepiride in El-Sheikh 2019 [58], Propolis in El-Sharkawy 2016 [57], *Balanites aegyptiaca* in Rashad 2017 [64] or locally applied therapy (intravitreal injections in Ghoneim 2013 and Saeed 2013 [78, 79] or local treatment of diabetic wounds in Yakoot 2019 [81]).

---

Moreover in this category substances were included, which can be summarized as dietary supplements including various vitamins (Vitamin D in Anyanwu 2016 [53] and Vitamin B in Elbarbary 2019 [71], fermented papaya in Somanah 2012 [80]), trace elements (e.g. Zinc in Anderson 2001 [28, 65]) and other substances (Carnosine in Elbarbary 2018 [73]) and its effects on glycemetic control.

#### **4.1.6 Intervention effects**

None of the studies reported results on **mortality**.

Two RCTs (Adibe 2013 and Mash 2015) reported results on **quality of life** [30, 31, 51, 52]. Both RCTS investigated the efficacy of different educational strategies to improve understanding and self-care for patients with DM2, but only one study reported an improved quality of life as a result of a structured self-care education program by pharmacists and nurses over 12 months [51, 52]. Adibe 2013 showed an improvement of quality of life (QoL) of  $0.86 \pm 0.12$  vs.  $0.64 \pm 0.10$  ( $p = 0.0001$ ) [51, 52].

**Hospital admission** was reported in two RCTs [27, 49, 50]. Abaza 2017 stated no difference between the groups [49, 50]. Chraibi 2017 stated less visits to healthcare professionals over 20 weeks for patients with DM2 with patient-driven compared to physician-driven titration of insulin ( $4.8 \pm 0.65$  vs.  $7.5 \pm 1.42$  visits / patient) [27].

**Intensification rates** of therapy was reported in Fairall 2016, a nurse-led intervention RCT, showing no intensified treatment for patients with diabetes in the intervention group over 14 months [33].

**Treatment adherence** was reported in 4 RCTs [29, 49, 50, 53, 75]. Adjei 2015 was able to improve compliance with appointment dates in the intervention group with electronic reminders (97.8 % vs. 89.4 %  $p=0.01$ ) [75]. Another cluster-RCT Labhardt 2011 stated better retention rates and adherence of patients with incentives or reminder letters (IG1 + IG2 vs. CG: 38 % vs. 35 % vs. 10 %; MD 26 (14 to 42)) [29]. Abaza 2017 found a significant higher treatment adherence of the intervention group, which received reminder messages [49, 50]. Anyanwu 2016 measured treatment adherence by tablet counting [53].

**Adverse effects and complications** were reported in 14 RCTs [26, 27, 40, 41, 43, 45, 55, 63, 69, 72, 73, 78, 79, 81]. Ibrahim 2014 could especially show a benefit concerning neonatal hypoglycaemia comparing metformin vs. insulin in treatment of GDM or pre-existing DM in pregnant patients [45]. Similar results concerning neonatal hypoglycaemia and neonatal ICU admission were shown in Ashoush 2016, which included women with GDM and randomized metformin vs insulin [43]. However, the control group had a lower rate of headache reported [43]. Furthermore Ashoush 2016 stated no significant non-inferiority of Metformin during pregnancy concerning the mode

---

and gestational age at delivery, fetal macrosomia, neonatal hypoglycaemia and admission to the Neonatal Intensive Care Unit. Regarding the maternal weight gain Ashoush 2016 stated a lower rate in the Metformin group  $4.4 \text{ kg} \pm 0.6 \text{ kg}$  vs.  $5.1 \text{ kg} \pm 0.8 \text{ kg}$  ( $p = 0.001$ ) [43].

Elbarbary 2016 was successful in showing a benefit for the intervention group using an insulin pump based therapy during Ramadan fasting with suspension activation vs. without activating the low glucose suspension activation regarding the number of hypo- and hyperglycemic excursions [72]. Elbarbary 2018 did not report any adverse effects, but a benefit for intervention group concerning the HbA1c after 12 weeks [73]. Malek 2015 stated similar rate of hypoglycaemia comparing basal-bolus insulin trice daily biphasic insulin over 50 weeks [26].

Some RCTs focused on diabetes related complications, for example Yakoot 2019, were patients with limb threatening ulceration were included and significant improvement on the healing rate was showed [81]. Nettleki 2015 also examined the healing rate of ulcers by applying phototherapy on either the ulcers themselves or regional lymphatic nodes combined with standard podiatric management vs. placebo phototherapy plus standard podiatric management. In this RCT no adverse effects were reported. However, only 7 patients were included [63]. Saeed 2013 was successful showing a significant difference regarding the best-corrected visual acuity and central foveal thickness in patients with diabetic macular edema [79].

**Cost effectiveness** only has been investigated in four RCTs [27, 30, 31, 43, 51, 52].

Adibe 2013 showed a benefit for the intervention group which received structured self-care education [51, 52]. Mash 2015 showed an incremental cost effectiveness ratio of 1862 Dollar/ Quality Adjusted Life Years (QALY) gained [30, 31]. Chraibi 2017 and Ashoush (2016) also showed a benefit for the intervention group [27, 43].

**Glycemic control** was reported in 7 RCTs for patients with DM1, in 4 RCTs for GDM, 26 RCTs for DM2 and in 1 RCT for patients with prediabetes.

Of the 7 RCTs with interventions on DM1, 5 were successful in improving the glycemic control (Abdulrhman 2013, Elbarbary 2018, Elbarbary 2019, Salem 2010, Van der Hoogt 2017)- [38, 40, 71, 73, 74]. Ashoush 2016 and Embaby 2016 included patients with GDM and showed an improvement in glycemic control [42, 43]. Ibrahim 2014 included patients with GDM and pre-existing DM and stated an improvement of the glycemic control [45]. Beyuo 2015 showed a significant difference in the 2-hour post prandial blood glucose (2 HPG), but no difference in fasting blood glucose (FBG) between the groups [44]. Krawinkel 2018, the only RCT on prediabetes did not show any difference regarding the HbA1c after 8 weeks [39].

A total of 33 RCTs reported results on HbA1c. 26 of them included mainly patients with DM2 and are graphically presented (see Figures 4-6).

A total of six out of 11 RCTs on educational strategies for patients with DM2 showed clinically relevant changes of HbA1c with significant differences between intervention groups and a higher decrease of HbA1c in the intervention group of at least 0.25 % (Amendezo 2017, Essien 2017, Mash 2015, Takenga 2014, Tawfik 2016, Debussche 2018) [30, 31, 54, 59, 67, 68, 77] (Figure 4). Successful interventions included various lifestyle education approaches (e.g. Amendezo 2017, Debussche 2018, Essien 2017, Tawfik 2016 [54, 59, 68, 77]), and telemedical approaches (Takenga 2014 [67]). For instance, Amendezo 2017 evaluated the efficacy of structured monthly lifestyle education sessions to improve glycaemic control for patients with DM2 in Rwanda with resulting lower HbA1c of -0.72% (95 %-CI -1.14 to -0.30) after 12 months compared to standard care [59].

**Figure 4: Efficacy of educational and nutritional as well as nurse led interventions strategies on HbA1c in patients with DM2**

Strategies to enhance physical activity were successful to lower HbA1c in two RCTs where patients with DM2 were given goals to accumulate 10.000 steps per day (Fayehun 2018 [60] MD -0.56 %; 95 %-CI -0.71 to -0.41) or they allocated to rebound exercise (Maharaj 2016 [48]; MD -1.24 %; 95 %-CI -1.74 to -0.74) compared to normal or sedentary activity habits. No difference was stated in two other RCTs between incremental exercises and education (Van Rooijen 2004 [70]) and exercises with different intensities (Yan 2014 [46]). (Figure 5).

**Figure 5: Efficacy of strategies to enhance physical activity**

Figure 6 presents effects of drug or nutritional strategies on HbA1c in patients with DM2. Three out of five showed clinically relevant changes of HbA1c [56–58]. El-Sharkawy 2016 analysed scaling and root planning of patients with severe periodontitis combined with propolis vs. same procedure but placebo controlled (MD -1.60%; 95% CI -2.22 to 0.98) [57]. EL-Sheikh 2019 compared glimepiride and L-Carnitine vs. glimepiride alone and showed a benefit for the intervention group (MD -2.09 %; 95 & CI -3.90 to 0.28) [58]. El-Haggar 2015 compared glimepiride and ketotifen vs. glimepiride alone (MD -0.75 %; 95 % CI -1.09 to 0.41) [56]. Anyanwu 2016 compared Vitamin D3 supplements over 12 weeks with placebo [53] and Chraibi 2017 analysed the effectiveness of patient driven vs. physician driven titration of Insulin as part [27].

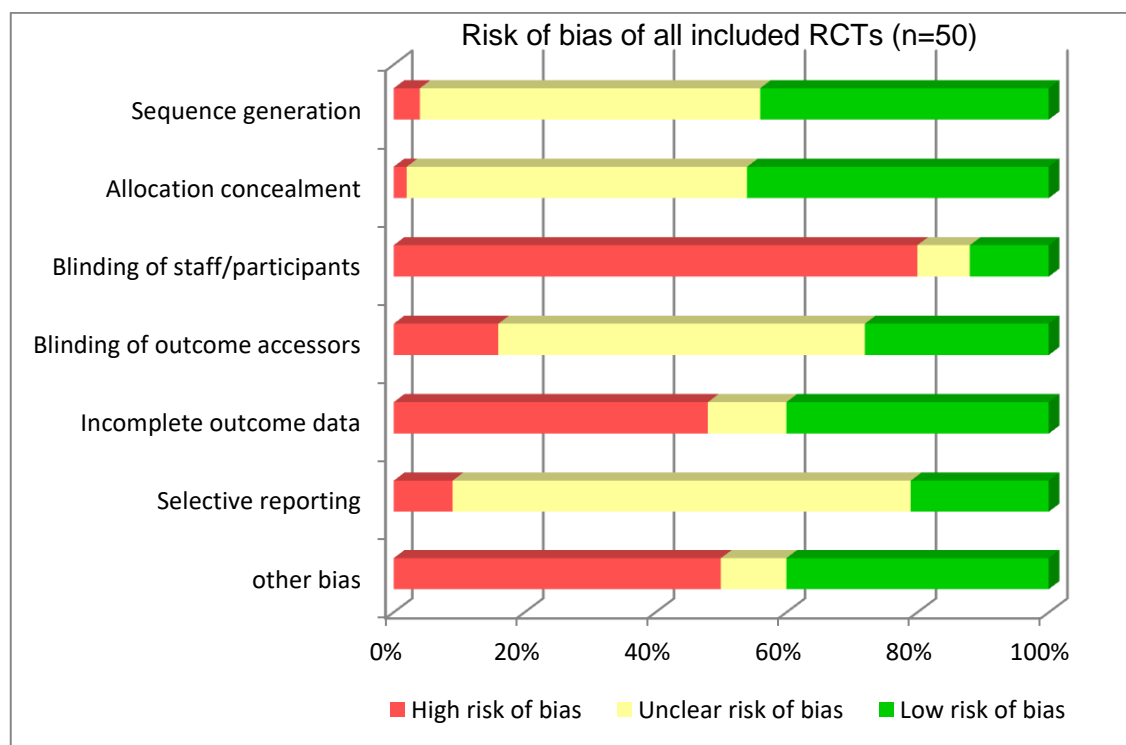

**Figure 6: Effects of drug or nutritional strategies on HbA1c in patients with DM2**

Some RCTs on DM2 with HbA1c as an outcome were not graphically demonstrated [26, 28, 32, 33, 55, 65, 69, 80]. Of those, only Tsobgny-Tsague 2018 was successful in demonstrating a better glucose control of the intervention group which received a periodontal treatment [69]. Fairall 2016, a nurse led intervention stated a benefit of HbA1c values in the range between 7-10 % [33]. Steyn 2013, Distiller 2014, Malek 2015 and Anderson 2001 reported no difference between the groups [26, 28, 32, 55, 65] and Somanah 2012 had incomplete data [80].

## 4.2 Risk of bias

None of the included studies were categorized as low risk of bias in all seven domains. 22 RCTs (44 %) of the studies fulfilled the criteria for low risk of bias concerning

random sequence generation, two RCTs (4 %) were assessed as high risk. EL-Shamy 2018 used a non-probability sampling method on the basis of the hospital admission code [41] and Nteleki 2015 randomized different ulcers in the same patient but not the patients from each other [63]. 26 RCTs (52 %) remained unclear. Bias due to allocation concealment was classified as low in 20 RCTs (46 %), high in one RCT (2 %), El-Shamy 2018 [41], and remained unclear in 52 %. Performance bias due to a lack of blinding of participants and personnel was judged as low in six RCTs (12 %), high in 40 RCTs (80 %), and remained unclear in four RCTs (8 %). Detection bias due to blinding of the outcome assessors was classified as low in 15 RCTs (30 %), high in eight (16 %) and unclear in 28 RCTs (56 %). Incomplete outcome data was assessed as low in 20 RCTs (40 %), as high in 24 RCTs (48 %), and stayed unclear in six RCTs (12 %). Reporting bias due to selective outcome reporting was assessed as unclear in the majority of the cases due to missing a protocol. In those RCTs where a protocol was available, it was judged as low in 11 RCTs (21 %) and as high in five RCTs (9 %). Further limitations were included in the last category “other bias” here 19 RCTs (40 %) were judged as low risk and 26 RCTs (50 %) were classified as high risk, five RCTs (10 %) remained unclear. The detailed judgement of each RCT is available in the supplemental material (Table 3), an overview is presented in Figure 7.

**Figure 7: Overview on the judgement of the risk of bias of all included RCTs (n=50) on the basis of the Cochrane risk of bias tool in seven specific categories**

---

## 5 Discussion

This review summarizes the available evidence for strategies to prevent, diagnose and treat diabetes in African countries.

50 RCTs conducted in Africa were identified, which were unequally distributed among the continent. Even though RCTs on prevention, diagnosis and treatment of diabetes were searched for, predominantly RCTs on treatment and on secondary or tertiary prevention and only a few on diagnosis and primary prevention were identified. Most of the RCTs were conducted in urban regions and only 9 out of 50 RCTs were conducted in a primary care setting. The quality of the included RCTs was limited, mainly due to low numbers of participants resulting in a limited precision of the results and non- or incomplete reported information. Still some promising interventions were identified, which could be useful for planning future research adapted to the local circumstances.

The fact, that the majority of the included RCTs were published within the last 5 years seems to indicate an increasing focus on diabetes research in some African countries.

Within the African continent, consisting of 54 countries, regional differences were observed: Most of the included RCTs were conducted in the North African region, especially in Egypt, followed by South Africa and Nigeria belonging to West Africa. Egypt is the country with the highest prevalence of diabetes of the African continent [12]. This might be related to economic expansion and urbanization, but also due to specific dietary issues (e.g. white bread, polished rice, trans fat), reduced physical activity due to prohibition of exercise in public places, shortage of exercise facilities, poor physical education in schools. Poor diet and physical inactivity are causing a high rate of overweight and obesity among the Egyptian population. Also the high rate of Hepatitis C infection might contribute to the comparatively high rate of diabetes in Egypt [82, 83]. Attention bias cannot be excluded as the prevalence of DM is high in Egypt but the rate of undiagnosed diabetes cases compared to the rest of Africa is less than the average [12, 84, 85].

All included RCTs on DM1 patients were conducted in Egypt except of one which was conducted in South Africa [40]. Those results are comparable to the statistics of the IDF [12]. The prevalence of diabetes seems to be higher in the North African region compared to the rest of Africa [84, 85]. Nevertheless the rate of undiagnosed patients with diabetes is estimated to be almost 45 % in North Africa compared to almost 60 % in rest of Africa [84, 85]. This distribution might be a result of a difference in social, economic, and genetic disparities [86]. The rate of undiagnosed diabetes cases may be related to the development level of the health care system and to a lack of awareness in the general population [87]. The high rate of undetected cases of diabetes signalize

---

a high need for research and implementation of diabetes screening strategies in the African context. Webb 2015 and Utz 2018 are RCT on screening for diabetes and diabetes related complications in primary care settings [34, 36, 37]. Only one RCT on primary prevention was identified, including people with prediabetes but the proportion of individuals progressing from pre-diabetes to diabetes has not been evaluated [39]. Interventions on primary prevention of diabetes, especially DM2, including strategies on lifestyle modification mostly require a long follow-up period and a rather high number of cases to analyze diabetes incidence [88]. In both cases including not only RCTs, but also other study types are needed [89].

The broad majority of included RCTs was conducted in urban settings, this is likely due to the better availability of research and health care infrastructure. The consequence is a limited generalizability of the results and a neglect of rural populations needs and a higher rate of undiagnosed diabetes [87]. Health care workers, including doctors and nurses seem to rather provide services in urban areas leading to an even higher deficit of health care access in rural areas and consecutively a lower life expectancy and poorer health status of the rural population [90, 91].

Africa is facing a shift from communicable to NCDs like diabetes resulting in a double burden for the whole continent [3, 6, 7]. However, strategies including nurse-doctor-teams which helped to cope with communicable disease like HIV may also be applicable to NCDs [92]. Nurse-led interventions, enhancing the primary healthcare capacity and the introduction of clinical guidelines and structured programs for detection and evidence based treatment of DM are needed to abolish the large undersupply [93, 94].

There is a strong need for context specific guidelines since eligible guidelines from high income countries may not be transferable to LMIC [95]. Steyn 2013, a cluster RCT from South Africa evaluated the introduction of a national guideline for diabetes care in nine community health care centers in South Africa [32]. After one year, the intervention had no impact on diabetes control. The staff criticized that these recommendations were rather idealistic and not realizable [32]. Modifying international guidelines to the socioeconomic context, human resources, especially well-trained health care professionals and infrastructure of Africa countries with a focus on clinical practicable strategies may be a better plan to improve diabetes care.

Education is the basis and essential to prevent or delay the manifestation of diabetes or diabetes related complications [96]. Patients empowerment being achieved through a good enlightenment may motivate each individual for a better control of their disease and is an essential component of the management of chronic diseases [97].

---

A couple of effective RCTs on education were included in the current work. Essien (2017) showed the efficacy of an intensive and systematic disease self-management education program in Nigeria improving the HbA1c value [77]. Amendezzo 2017 succeeded in achieving clinically relevant results concerning glycemic control also by structured monthly lifestyle education sessions in Rwanda [59].

Tawfik 2016 also succeeded in showing the impact of communicating cardiovascular risk in patients with DM2 on HbA1c [68]. Debussche 2018 also analyzed structured culturally tailored education delivered by trained peer educators and proved a significant benefit for the interventional group concerning the HbA1c [54]. All studies had in common, that they were adapted to the local circumstances. Those interventions are potentially replicable at other levels of African health care systems and in other LMICs, where nurses can run respective programs. Further task-shifting to nurses and other health workers in primary health care management of NCDs such as diabetes, might improve health care effectiveness and efficiency [98]. In countries with a lack of doctors, the role of the nurses in NCD care should be expanded, especially in LMIC, not only for education as an intervention, but also for improving the diagnostic and for treatment of diabetes. Benefits of nurse-led care regarding clinical effectiveness and cost-effectiveness of chronic diseases in high income countries is well recognized [99–102], however evidence for LMICs is still limited [95, 103]. In total, three RCTs on nurse-led intervention were included and none of them evaluated the cost effectiveness, even though the economic aspect should be evaluated as well [29, 33, 61].

Adibe 2013 evaluated a structural self-care education program implemented by pharmacists with the cooperation of physicians and nurses and was successful in showing a benefit of incremental gain in QALYs and reduced costs compared with the control group after one year [51, 52]. More economic evaluations like this should be implemented in African countries to assess the efficacy of nurse-led care [104].

In times of growing digitalization also other sources should be evaluated. Takenga 2014 combined self-management of diabetes with telemedical approaches and stated a significant decrease of the HbA1c [67]. Information and communication technologies might also have great potential to improve the accessibility of the African population to high quality health care services where the human resources are limited [67, 105]. Lifestyle focussed messages might be a low cost and effective option for keeping the patients motivated to adhere to a healthy lifestyle [105]. The number of people having access to mobile services is expected to rise during the next years [106]. The application of telemedicine in different parts of diabetes management has been evaluated in previous studies before and has shown promising results [107, 108]. Still,

---

the implementation of a digital health ecosystem is a complex process with many challenges to overcome [109, 110]. Currently the COVID-19 pandemic has forced all nations to implement alternative and more flexible strategies including for example telemonitoring and teleconsultation for continuing care of NCDs [111, 112].

This can indicate options or the need for assessing these approaches in the regional context.

Of the strategies to enhance physical activity, Fayehun 2018 managed to improve glycemic control by setting the goal to accumulate 10.000 steps per day, an intervention which does not require any cost intensive infrastructure and still managed to show significant decrease in HbA1c levels after 4 weeks [60].

Another important aspect is that originally pre-planned primary outcomes were mortality and quality of life, but study results are only available on quality of life in two RCTs [30, 31, 51, 52]. Mortality is not reported in any of the included RCTs. This could be due to the fact that overall surviving time with diabetes is higher than the follow up time of most of the RCTs. Nevertheless long-term glycemic control, being represented by the HbA1c value is one of the strongest clinical-outcome indicators of efficient diabetes management and health outcomes [113]. It is easy to measure and gives a good overview over individual's average blood glucose levels in the previous 3 months [113, 114]. Compared to mortality, which requires long follow up periods, the HbA1c value is more easily measured and therefore might explain why the majority of the included studies chose it as a primary outcome parameter.

Regarding the substance-based studies, it has to be noted that big international multicenter pharmacological studies with few centers in African countries were excluded, resulting in a rather small amount of included studies (Table 1). Several studies where metformin was tested during pregnancy were included. For example, Ashoush 2016 showed a significant result regarding the glycemic control in the interventional group using metformin plus if needed insulin vs. insulin only as a control group. Concerning the maternal hypoglycemia the results were also in favor of the intervention group with a prevalence of 6.3 % vs. 12.5 % [43]. Ibrahim 2014, a RCT conducted in Egypt including also patients with GDM or pre-existing DM2, demonstrated a significant better glycemic control and a significant lower rate of maternal hyperglycemia in the metformin group [45]. Both showed a benefit of metformin. Their results are similar to the findings of an international RCT, which showed a comparability of Metformin to Insulin during pregnancy without increasing perinatal complications and better results for Metformin in achieving a faster glycemic control and an overall lower weight gain during pregnancy [115]. Another meta-analysis proved that metformin is not associated with increased perinatal complications

---

compared with insulin [116]. Still long term outcome information is limited and this is the reason why insulin is still the first line therapy of diabetes in pregnancy [117].

Besides the identified studies, there are other approaches, which are very well established and likely can be transferred to an African setting. For example the disease management programs (DMPs), which intended to improve the quality of care of patients suffering from chronic disease [118]. Those structured programs might help to identify or even prevent the diabetes related complications at early stage through regular checkups. This would allow adjusting or adapting treatment strategies in time.

### **5.1.1 Strength and limitations**

Systematic reviews and meta-analyses have become progressively important in health science [20]. Clinicians as well as researchers read them to get an overview on pre-existing information on a certain topic in order to conduct new studies as well as to keep up with a certain field [20].

We strictly followed the PRISMA guidelines [20] in this project to guarantee a high standard of reporting. A protocol has been registered and published in the PROSPERO (CRD42019122785) prior to starting this work.

This systematic review includes RCTs as the gold standard for determining causal efficacy of medical interventions and their benefit assessment [119], without time constrictions, but language restrictions. Language bias was shown to be unlikely. Despite the high linguistic diversity on the African continent, the most spoken language besides English are Arabic and French [120]. Nevertheless, we did not exclude any studies due to their publication language.

Four databases were searched, but further African publications might only be listed in local databases that had not been searched for this review. The effect of this bias is assumed to be small since high quality studies are published in internationally indexed journals [21]. The ICTRP also includes the Pan African Clinical Trial Registry (PACTR) representing a local register which aims to be a comprehensive database of all planned, ongoing or completed clinical trials in African countries [121].

Concerning the risk of bias, often there was insufficient information on the different categories and thus this bias had to be often judged as “unclear”. The CONSORT statement aims to improve this in future RCTs [22].

The included entities of diabetes (DM1, DM2, GDM) cover more than 98 % of the patients with diabetes [122].

On the baseline data, it has to be noted that only the half of the studies reported information on duration of diabetes at baseline, but this is a major risk factor for developing diabetes related complication [123]. External validity might also be limited

---

by the focus on mainly urban areas. People living there have a better access to health care are more likely to be diagnosed at an early disease stadium. People living in rural ares are rather be diagnosed at an advanced state of disease and are more likely to already suffer from diabetes related mirco-and/or macrovascular complications [87]. The avoidance of risk factors, an early detection and an early treatment of diabetes have an enormous benefit on the course of disease and on the financial burden [10, 124].

---

## 6 Conclusion

This systematic review shows an increasing number of studies due to a rising prevalence and awareness of diabetes in African countries. But the number of RCTs to improve detection, treatment, adherence and prognosis of African patients with diabetic illnesses is still low. The majority of RCTs included in this review were interventions on the treatment of diabetes being part of secondary and tertiary prevention and not on the primary prevention or diagnostic. Both important aspects to control diabetes in LMIC like the countries in Africa with a special need of locally feasible interventions. Available RCTs might not be representative for all people in Africa, as there are focusing only on a few countries and a rather urban setting. More RCTs in rural settings are necessary, however especially there, a shortage of human resources like health care workers, nurses, basis technologies for diagnostic and medication is still a challenge for conducting research and implementing strategies on diabetes management.

It is crucial to plan and implement more RCTs on the effectiveness of different prevention and treatment strategies. One major implication for practice is the expanded role of doctors and nurses in primary health care to improve the diabetes care in Africa and the evaluation of digital health services to improve health care services in places, which are facing a shortage of professionals.

The empowerment of the patients as well as the whole population is urgent to achieve an increased awareness and understanding of the disease, leading to a higher willingness to change life style and overall adherence to the treatment and regular checks.

Health systems must ensure technical and financial resources to screen and care for patients with diabetes. An improvement in the prognosis of patients with diabetes in African countries requires the implementation of locally adapted guidelines aiming to identify diabetes and its complications as early as possible.

The identified RCTs offer effective strategies as a basis for local guidelines tested in African countries, including non-pharmacological strategies on education and lifestyle modification including nurse-led interventions, and pharmacological strategies with the particularities resulting from the wide diversity of the African population.

## Theses

1. This systematic review implicates an increased awareness of diabetes in African countries during the last years, as the majority of the included RCTs had been published within the last 5 years.
2. The number of RCTs, which improve detection, treatment, adherence and prognosis of African patients with diabetic illnesses is still low. A total of 50 RCTs with all together 9331 patients were included.
3. Apparently, there seems to be a lack of evidence of Eastern and Central Africa. The included RCTs were set in 15 of the 54 African countries with a focus on the Northern and Southern African region, especially Egypt and South Africa.
4. The broad majority of included RCTs were conducted in urban settings, stating an underrepresentation of RCTs in rural settings.
5. It is necessary to integrate the patient in disease-associated decisions. Interventions to strengthen the empowerment on the basis of an improved knowledge, motivation and capacity to take control of their disease seem to be very promising.
6. A strong collaboration of doctors and nurses is necessary to improve diabetes care. Moreover, the tasks of the nurses could be redefined and expanded in countries with a comparably few physicians as a measure for improvement of detection, treatment, adherence and prognosis of patients with diabetic illnesses.
7. In times of growing digitalization, information and communication technologies might also have great potential to improve the accessibility of the African population to high quality health care services, where the human resources are limited.
8. An improvement in the prognosis of patients with diabetes in African countries requires the implementation of locally adapted guidelines aiming to lower the rate of undiagnosed diabetes, leading to earlier detection and effective actions to prevent or delay the onset of diabetes and its consecutive complications.

## Characteristics of included studies

Table 2: Overview on characteristics of included studies

Study name Design	Setting	Population		Intervention vs. Control	Outcomes	Results
	Place, environmental/ health care setting (primary vs. other care) and time	Inclusion / Exclusion criteria	Randomized participants, gender, age, type and length of diabetes, diagnostic criteria, BMI, comorbidities	Description (n=), Duration	primary and secondary	Longest follow-up period with intervention effects: Intervention (IG) vs. Control (CG), intervention effect (95%-CI, p-value)
<b>Abaza 2017 [49, 50]</b>  RCT	Egypt, urban, tertiary care, 03/2015 - 05/2013	DM2, mobile phone, capable to read SMS or live with someone who could read	n=73 gender: 56 % females age (yrs): 51.5±9.2 HbA1c (%): 9.7±2.7 random Blood glucose (mg/dl): 88.1±16 the majority had had diabetes for > 1 yr hypertension: 41.1 % on insulin: 19.2 % suffer diabetes complication: 80.8 %	MUST diabetes awareness program paper-based educations material <u>IG (n=34):</u> daily messages and weekly reminders addressing various diabetes care categories vs. <u>CG (n=39):</u> paper-based educations material <u>Duration:</u> 12 wks.	<u>Primary:</u> change in Hba1C <u>Secondary:</u> Random blood glucose levels, body weight, adherence of treatment and medication, diabetes self-efficacy and knowledge, rate of hospital/ER visits, frequency of measurements, regular exercise, patients confidence in healthcare provider and satisfaction, healthcare provider's reputation	After 12 weeks: <u>HbA1c (%)</u> : • No differences: 8.73 ±1.98 vs. 8.84±2.40 (p=0.838) • MDa: 0.290 (-0.402 to 0.983; p = 0.406) • Benefit for IG: 47 vs. 15 % achieved the targeted 1% drop (p = 0.003) <u>Random blood glucose (mg/dl):</u> • 181±65 vs. 201±87 (p=0.288) <u>Treatment adherence:</u> • SCl: Benefit for IG: 3.42±0.48 vs. 2.52±0.49 (p<0.001) • Morisky: Benefit for IG: 3.76±0.55 vs. 2.74±1.07 (p<0.001) <u>no hospital /ER admission (%)</u> : No differences: 100 vs. 89.7 (p=0.118)
<b>Abdulrhman 2013 [38]</b>  Cross-over RCT	Egypt, urban, tertiary care,	DM1, age > 2 yrs, HbA1c< 10 %  no renal or hepatic impairment, coexisting	n=20 gender:50% females age (yrs): 11.3 ± 4.3 HbA1C (%):7.21 %±	<u>IG to CG (n=10):</u> Honey consumption (0.5 ml/kg body weight per day) vs.	<u>Primary:</u> serum lipids, c-peptide <u>Secondary:</u> anthropometric measures (e.g. BMI),	After 12 weeks: (IG/CG vs. CG/IG): <u>HbA1c (%)</u> : • better with CG/IG: 6.7±0.9 vs. 5.9±0.8 (p<0.01) • no differences in change in

Study name Design	Setting	Population	Intervention vs. Control	Outcomes	Results	
	01/2010 - 10 / 2011	diseases or therapies that may affect body weight or serum lipids	0.76 fasting glucose (mg/dl): 154.5±22.5 duration of diabetes (yrs): 4.7±4.5	<u>CG to IG (n=10):</u> changed after 12 wks and received than honey <u>Duration:</u> 24 wks.	fasting and 2h- postprandial serum glucose, HBA1c, serum lipid profile	period 1: -5.83 ± 13.66 vs. 2.94±8.82 (p=0.105) <u>Fasting serum glucose (mg/dl):</u> • better with CG/IG: 142.7 ±26.6 vs. 116.7±19.4 (p<0.01) • better with IG/CG in period 1- 21.51 ± 10.84 vs. -0.08±5.14 (p=0.001)
<b>Adibe 2013</b> <b>[51, 52]</b>  RCT	Nigeria, urban, tertiary care	DM2, age≥ 18 yrs with oral hypoglycemic and / or insulin therapy  no pregnancy	n=220 gender: female 58 % age (yrs): 52.6±7.9 duration of diabetes (yrs): 4.7±2.5, 60.5% with diabetes > 5 yrs on insulin: 13.6 % hypertension: 60.5 %	<u>IG (n=110):</u> structured self-care education and training program by pharmacists and nurses vs. <u>CG (n=110):</u> usual / conventional care <u>Duration:</u> 12 months	<u>Primary:</u> incremental cost-utility ratio, net monetary benefit <u>Other:</u> quality of life	After 12 months: <u>Quality of life:</u> • improved QoL: 0.86 ± 0.12 vs. 0.64 ± 0.10 (p=0.0001) improved single attributes except “hearing” functioning of the patients <u>Costs:</u> • benefit of \$0.7625±0.15 vs. \$0.6425± 0.15 QALY per patient per year (MD: \$ 0.12 (0.07to0.16) • incremental cost-utility ratio of \$571 per QALY gained
<b>Adjei 2015</b> <b>[75]</b>  RCT	Ghana, urban	DM	n=200 gender: 64.5% female age (yrs): < 50 yrs: 63 % > 50 yrs: 37 % fasting glucose (mmol/l): 10.4±3.8	<u>IG: (n=100):</u> electronical reminder for clinical appointments of patients + alert system for abnormal laboratory results vs. <u>CG: (n=100):</u> usual diabetes care, paper based method <u>Duration:</u> 6 months	<u>Primary:</u> Compliance with appointment dates <u>Other:</u> metabolic risk factors (SBP, DBP, pulse rate, FBG), BMI	After 6 months: <u>Adherence to appointment schedules (%)</u> • Benefit for IG: 97.8 vs. 89.4, p=0.010 <u>FBG (mmol/l):</u> • Benefit for IG: 8.04±2.14 vs. 8.85±2.63; MD 0.4 ( -0.593 to - 0.365, p=0.022)

Study name Design	Setting	Population	Intervention vs. Control	Outcomes	Results	
<b>Amendezo 2017 [59]</b>  RCT	Rwanda, urban, tertiary care	DM2>3mth, age>21yrs  no pregnant or pat. with severe co-morbid illnesses.	n=251 gender: 69.3% females age (yrs): 50.9 (±10.9) HbA1c (%): 8.98 (8.6-9.3) fasting glucose (mmol/L): 8.97 BMI (kg/m <sup>2</sup> ): 27.9 (27.0-28.5) duration of diabetes : <10 yrs 73.7%, >10yrs: 16.3%	<u>IG (n=115)</u> : standard of care plus monthly lifestyle education sessions of 45 min duration vs. <u>CG (n=108)</u> : standard care <u>Duration</u> : 12 months	<u>primary</u> : difference in HbA1c <u>secondary</u> : fasting glucose, systolic and diastolic blood pressure, BMI	after 12 months: <u>HbA1c (%)</u> : <ul style="list-style-type: none"> <li>Benefit for IG with median reductions by 1.70 (-2.09 to -1.31) vs. 0.52 (-0.95 to -0.10); MD: -0.72 ( -1.14 to -0.30; p&lt; 0.001)</li> </ul> <u>Fasting glucose (mmol/L)</u> : <ul style="list-style-type: none"> <li>6.9 (6.45 to 7.36) vs. 9.02 (8.18 to 9.87) (p&lt;0.001)</li> </ul>
<b>Anderson 2001 [28, 65]</b>  RCT	Tunesia, urban, other care	DM2 ≥ 5y, age< 65 yrs, fasting glucose > 8 mmol/l and HbA1C > 7,5 %  no pregnant or lactating women, receiving trace element supplements in past 3 months, with gastric or diuretic treatment, acute renal, acute infection or recent surgery	n=110 age (yrs): 53.2 ±1.62 HbA1c (%):8.82±0.31 fasting glucose (mmol/l): 11.45±0.08 BMI (kg/m <sup>2</sup> ): 29.15±0.15 duration of diabetes (months): 73.6±6.3	<u>IG 1 (n=27)</u> : 30 mg Zinc /d vs. <u>IG 2 (n=27)</u> : 400 µg Chromium/d vs. <u>IG 3 (n=27)</u> : 30 mg Zinc + 400 µg Chromium /d vs. <u>CG (n=29)</u> : placebo <u>Duration</u> : 6 months	Not specified: HbA1C, fasting glucose plasma concentrations of zinc, copper, selenium, urinary chromium and zinc, Plasma thiobarbituric acid reactive substances, copper-zinc-superoxid dismutase, selenium - glutathione peroxidase	Change over 6 months: <u>HbA1c (%)</u> : <ul style="list-style-type: none"> <li>7.7±0.3 vs. 7.4±0.26 vs. 8.1±0.3</li> <li>CG: not reported</li> </ul>
<b>Anyanwu 2016 [53]</b>  RCT	Nigeria, urban, other care	DM2, age 35-65 yrs on oral antidiabetics with vitamin D deficiency and poor glycemic control (HbA1c > 6.5 %)  no patients on insulin, pregnancy, renal insufficiency, chronic	n=42 gender: 57.6 % female age (yrs): 51.8±2.05 HbA1c (%): 7.88 fasting glucose (mg/dl): 152.8±56.5	<u>IG (n=21)</u> : Vitamin D3 supplements (3000 IU daily) vs. <u>CG(n=21)</u> : placebo <u>Duration</u> : 12 weeks	<u>Primary</u> : HbA1c <u>Other</u> : fasting glucose, levels of serum Vitamin D, calcium, albumin, phosphate, creatinine, and alanine transaminase	Changes over 12 wks: <u>HbA1c (%)</u> : <ul style="list-style-type: none"> <li>MD (IG vs. CG): -0.66 (-0.161 to 0.29) vs 0.38 (-0.08 to 0.84);</li> <li>MD: -1.04 (-2.09 to 0.01)</li> <li>change from poor glycemic control (HbA1c&gt;6.5 %) to normal HbA1c (%): benefit for IF: 33.3 vs. -9.1 (p&lt;0.05)</li> </ul>

Study name Design	Setting	Population	Intervention vs. Control	Outcomes	Results	
		liver disease or alanine transferase > 5 times upper reference limit, tuberculosis, diarrheal, or malabsorption state			<u>fasting glucose (mg/dl):</u> <ul style="list-style-type: none"> <li>137.2±33.6 vs. 154±67.5</li> </ul> <u>patient adherence</u> (tablet counts, %): 62.2 vs. 59.9	
<b>Ashoush 2016 [43]</b>  RCT	Egypt, urban, tertiary care,  01/2014-11/2014	mothers with 26–32-week GDM (oral 2-h 75 G glucose tolerance test) singleton pregnancies, failure of satisfactory glycemic control despite adequate diet and exercise for ≥ 1 wk  no fetal anomalies on ultrasonography, other pregnancy complications, known intolerance to metformin or risk factors for lactic acidosis	n=95 gender: 100% female age (yrs): 31.85±3 HbA1c (%): 5.75 ± 0.55 75g OGTT(mg/dl) <ul style="list-style-type: none"> <li>fasting: 106.05±4.6</li> <li>1h:310.25±11.6</li> <li>2h:176.65±9.4</li> </ul> BMI (kg/m <sup>2</sup> ): 31.2±1.4	<u>IG (n = 47):</u> metformin (initial total dose 1000 mg/d with meals, increase by 500 or 850 mg every 1 or 2 wks toward target or up to a maximum dose of 2500 mg/d until delivery, addition of insulin if needed vs. <u>CG (n = 48):</u> regular insulin + neutral protamine Hagedorn (3:7), starting dose of 0.7 units /kg / day, adjusted to achieve adequate glycemic control at increments of 1 unit/10 mg glucose higher than the desired cut-off, short action insulin whenever needed	<u>primary:</u> successful maternal glycemic control <u>Secondary:</u> maternal BMI, glycemic control parameters, maternal weight gained during pregnancy, side effects to metformin, mode of delivery, gestational age at delivery, neonatal birthweight, macrosomia, neonatal hypoglycemia, neonatal death, congenital anomalies, admission to neonatal intensive care unit	<u>fasting glucose during treatment (mg/dl):</u> <ul style="list-style-type: none"> <li>during the last wk: 78±3.1 vs. 79.9±3.7 (p=0.008)</li> <li>during the last 2 wks: 78.9±3.5 vs. 80.8±4.7 (p=0.029)</li> </ul> <u>maternal hypoglycaemia (%):</u> 6.25 vs. 12.5 (p=0.254) <u>neonatal hypoglycaemia (%):</u> 12.8 vs. 14.6 (p= <u>Maternal weight gain (Kg):</u> 4.4 ± 0.6 vs. 5.1 ± 0.8 (p=0.001) <u>neonatal congenital anomalies (%):</u> 2.1 vs. 2.1 p= 0.747 <u>headache (%):</u> 27.3 (metformin+insulin) vs. 5.6 (metformin monotherapy) vs. 0% (insulin monotherapy) <u>neonatal ICU admission (%):</u> 8.5 vs. 10.4 (p= 0.514) <u>Costs (Egyptian pounds):</u> 89.66±0.96 vs. 174.9±11.1 (for monotherapies)
<b>Asuako 2017 [76]</b>  RCT	Ghana, urban, tertiary care,  08/2015-03/2016	DM, age: 20-68 yrs, ambulant patients, without diabetes complications with < 150 minutes /wk of moderate physical activity no SBP > 140 or DBP> 90 mmHg, bilateral or	n=12 gender: 83% female age (yrs): 83% were btw. 46-55 yrs. fasting glucose (mmol/l):9.33 ± 5.7 BMI	<u>IG (n=7):</u> walking aerobic exercise sessions without treadmills (3/week) vs. <u>CG (n=5):</u>	FPG, Lipid profile, body weight, BMI	Change over 8 wks: <u>FPG (mmol/l):</u> Benefit for IG: 6.27 ± 0.91 vs. 8.00 ± 0.96; MD 1.73 (-1.88 to -1.59; p<0.001)

## Appendix

---

---

**Declaration under oath**

I declare under oath that this thesis is my own work entirely and has been written without any help from other people. I met all regulations of good scientific practice and I used only the sources mentioned and included all the citations correctly both in word or content.

---

## **Declaration of previous attempts at doctoral application**

I declare that I have not completed or initiated a doctorate procedure at any other university.

---

**Declaration concerning the truth of information given**

I declare that all information given is accurate and complete. The thesis has not been used previously at this or any other university in order to achieve an academic degree.

---

## **Acknowledgements**

At this point, I would like to thank all persons supporting me in the past years.

First, I want to express my special thanks to my supervisors, PD. Dr. rer. nat. habil. Susanne Unverzagt for her outstanding support and Prof. Dr. med. Thomas Frese, the director of the Institut of General Medicine, Faculty of Medicine at the Martin Luther University of Halle-Wittenberg for his great advice in the implementation of the entire work.

Secondly, I want to thank my family and dedicate this work to my father, Prof. Hagen Sandholzer for supporting me with great advice and encouraging me. You are an excellent father, mentor and instructor.

Furthermore, I want to say thank you to my brother, Dr. Maximilian Sandholzer and my mother, Dr. Ute Sandholzer, for their patience. I also want to thank my host father, Doug Spencer for his proofreading and advice on the English language in academic papers.

Finally yet importantly, I thank my fiance, Hasan Yilmaz for his unconditional support, constant encouragement and his patience while studying and working on this dissertation.

I am deeply grateful to be surrounded by such wonderful people.
