Numbering

All compounds retain the numbering used in the publications with the addition of an a–f depending on the reference in which they are reported (appendix 1 and 2).

Summary of numbering for ligands

Since several of the ligands of the type \( \text{Y} (\text{CH}_2 \text{CH}_2 \text{O})_x \text{CH}_2 \text{CH}_2 \text{Y} \) (\( \text{Y} \) is pyrazol-1-yl, pz; imidazol-1-yl, im or benzimidazol-1-yl, bim) are reported in more than one publication some ligands have more than one compound number, as summarized in the table below. 1,8-Bis(pyrazol-1-yl)-n-octane and bis[2-(pyrazolyl-1-yl)ethyl]thioether become \( \text{L}_2 \text{e} \) and \( \text{L}_4 \text{e} \), respectively, herein.

Numbering of non-commercially available ligands of the type \( \text{Y} (\text{CH}_2 \text{CH}_2 \text{O})_x \text{CH}_2 \text{CH}_2 \text{Y} \) in [c–e].

1. Introduction

1.1. Metallacrown ethers

Definitions

Crown ethers are macrocyclic compounds with oligoether, often ethyleneoxy, repeating subunits. Metallacrowns and metallacrown ethers share a number of structural similarities with their organic analogue crown ethers (Fig. 1).

![Crown ether, Metallacrown, Metallacrown ether](image)

**Fig. 1** Analogy between crown ether, metallacrown and metallacrown ether rings. M: transition metal ion fragment. X: ligating atom/moiety.

Metallacrowns are defined as cyclic structures with the ring transition metal ion fragments and nitrogen atoms replacing the methylene carbon atoms of crown ethers thereby giving rise to \(-(M-O-N)_n\) repeating subunits. As with crown ethers, metallacrowns can also contain modified subunits, \(-(M-O-C-N)_n\) for example. A large number of metallacrowns have been reported over the last decade incorporating a variety of metals and bridging ligands alike. Metallacrowns are often isolated with cationic or anionic guests present in the crown cavity.

Metallacrown ethers are cyclic structures with metal ion fragments incorporated in the backbone of a polyether macroring such that the metal is connected to the polyether backbone by a ligating moiety at either end of the polyether chain (X in Fig. 1). Metals that have been incorporated in metallacrown ether backbones include Mo(0), Ru(II), Pd(II), Pt(II), Ag(I), Au(I) and Hg(II). α,ω-Bis(phosphino) polyether compounds are the most popular choice of polyether ligand to date. Other ligating moieties reported include pyrazol-1-yl and N-heterocyclic carbenes (benzimidazolium and imidazolium), although these are less prevalent. The binding capacity of various metallacrown ethers has been examined with a limited range of cationic guests such as Li⁺ and Na⁺ ions.
Introduction

Host-guest interactions with ammonium ion guests

Host-guest interactions between crown ethers and ammonium ions were studied early on in investigations with crown ethers, although most investigations focused on ammonium or primary ammonium ion guests.\textsuperscript{7,8} Hydrogen bonding interactions between primary or some secondary ammonium ion guests and crown ether hosts often leads to the ammonium ion being bound perched above the average plane of the macrocycle,\textsuperscript{9} rather than in the ring cavity as is typical for most host-metal-cation guests (Fig. 2a). Dialkylammonium ions may also thread the cavity of suitably sized crown ethers and can subsequently preclude the formation of other interlocking molecules (Fig. 2b).\textsuperscript{10}

![Fig. 2 Perched (a) and threading (b) interactions between dialkylammonium ion guests and crown ether hosts.](image)

Amine bases are often employed in the synthesis of metallacrowns and their ammonium ions are subsequently frequently found in the cavity of the isolated metallacrown.\textsuperscript{11} Interactions between ammonium ions and metallacrown ethers are relatively unknown in the literature, only one example between an ammonium ion and a rhenium metallacrown ether has been reported.\textsuperscript{6e}

1.2. Complexes with anticancer properties

Platinum complexes with anticancer properties

Since the introduction of cisplatin as a widely used cancerostatic in 1978, two further platinum(II) cancerostatica, carboplatin and oxaplatin (Fig. 3), are in worldwide use for the treatment of cancer. The mechanism of action of cisplatin has been thoroughly studied.\textsuperscript{12} It is believed that cisplatin is activated intracellularly on aquation of the chloride leaving groups generating a highly reactive diaqua species that binds to DNA and subsequently activates various signal-transduction pathways.\textsuperscript{12,13} While investigation and discussion over the significance of the various binding interactions...
of the platinum(II) adduct to the double helix is ongoing, the result of the binding leads to either repair of the damaged DNA or cell death.\textsuperscript{12,13}

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{Fig3.png}
\caption{Widely used platinum(II) anticancer drugs and satraplatin.}
\end{figure}

The success of cisplatin in the clinic has lead to testing of new platinum compounds that have sought to improve upon the drawbacks and side effects associated with cisplatin.\textsuperscript{14} Platinum(IV) complexes are kinetically inert to ligand substitution relative to platinum(II) complexes and the design of platinum(IV) anticancer drugs has been encouraged by their potential as drugs that may be administered orally, a feature arising from their inherent inertness.\textsuperscript{15} However, to date, of the three platinum(IV) complexes to have entered clinical trials, iproplatin, ormaplatin/tetraplatin and satraplatin/JM216, only satraplatin remains in clinical trials (Fig. 3).\textsuperscript{14,15}

The design of new platinum(II) drugs has been dominated by a number of structure-activity ‘rules’, all of which are satisfied by the neutral cisplatin (Fig. 4a).\textsuperscript{16} The carrier ligand is any ligand inert to ligand substitution and is often an amine with at least one N–H bond. The anionic leaving groups $X^-$, often chloro ligands, generally undergo hydrolysis in the cell. It has, on the other hand, been shown that some platinum(IV) drugs, for example satraplatin,\textsuperscript{17} are reduced to platinum(II) complexes by common intra- and extracellular reductants.\textsuperscript{18} Reduction to what is generally believed to be an active platinum(II) complex has been shown to often result from the elimination of the axial ligands (in accordance with the discussion in the literature: plane with $N$-donor carrier ligand ‘equatorial’ and ligands above and below this plane are ‘axial’).\textsuperscript{19,20}

Thus there is no set of structure-activity rules for the design of platinum(IV) drugs but the vast majority are designed such that the resulting reduced platinum(II) species is active and thereby in accord with the platinum(II) structure-activity rules (Fig. 4b).

Furthermore, the axial ligands are often used as a means to alter the overall solubility/lipophilicity and reduction potential of the platinum(IV) complex in addition to acting as an extra site for the incorporation of bioactive molecules.\textsuperscript{21–23}

**Bioorganometallics**

Recently bioorganometallic chemistry has emerged as a new field distinct from bioinorganic chemistry.\(^{24}\) Within the scope of this field, and encouraged by the widespread usage of platinum cancerostatica, the design of new anticancer drugs based on metallocenes of titanium (Fig. 5a) and iron (Fig. 5b) has attracted significant attention.\(^{25}\)

**Fig. 5** Anticancer bioorganometallic (a) titanium, (b) iron and (c) ruthenium complexes.

In addition, ruthenium complexes with arene ligands (Fig. 5c) have been shown to possess remarkable activity *in vitro* and *in vivo*, are water soluble and, through variation of the different ligand types, show a wide range of activity.\(^{26}\) To date however no bioorganometallic complex has undergone successful clinical trials.

**1.3. Aims of the thesis**

Macro cyclic inorganic molecular structures related to crown ethers have received significant attention in recent years.\(^2\)–\(^6\) Metallacrown ethers are a relatively small area among metallamacrocycles. Complexes consisting of molybdenum(0) with \(\alpha,\omega\)-bis(phosphino) polyether ligands are the most frequent type of metallacrown ether
Introduction

reported and to date the properties of only a few other types of metallacrown ethers have been investigated.4–6 The pairing of platinum(II)/(IV) precursor complexes with α,ω-bis(azolyl) polyether ligands should afford a route to the preparation of a new family of platinum metallacrown ethers. Host properties of the platinum(IV) metallacrown ethers with guest ions such as dialkylammonium ions would extend the small range of guest ions commonly employed in metallacrown ether receptor studies.4a,d,6 The cancerostatic behavior of these platinum(IV) metallacrown ether complexes would be of interest since along with the known anticancer activity of platinum complexes, the polyether chain of the ligand may impart a degree of hydrophilicity to the complex overall, thus making it more amenable to biological media.

The results discussed herein can be partitioned into three main themes:

- The extent of the reactivity of [(PtBr₂Me₂)ₙ] with N-heteroaromatic compounds with at least two potential ligating nitrogen atoms and the propensity to form dinuclear complexes from mononuclear building blocks using these types of ligand.
- Examination of the reactivity of α,ω-bis(azol-1-yl) polyether ligands (azol-1-yl: pyrazol-1-yl, imidazol-1-yl or benzimidazol-1-yl) with platinum precursors and the preparation of metallacrown ethers with α,ω-bis(azol-1-yl) polyether ligands.
- To investigate the properties of these metallacrown ethers with α,ω-bis(azol-1-yl) polyether ligands, particularly their host properties and their potential as cancerostatica.
2. Results and discussion

2.1. Mononuclear platinum(II)/(IV) complexes

2.1.1. With N-heteroaromatic donors

Synthesis

The preparation of dibromodimethylplatinum(IV) complexes from the precursor complex [(PtBr₂Me₂)ₙ] in chloroform proved a simple and efficient means of preparing complexes of the type [PtBr₂Me₂(N=N)] (N=N is a bidentate N-donor ligand) 1a–4a and [PtBr₂Me₂(L)₂] (L is a N-heterocyclic monodentate ligand) 5a–10a, 1b and 1f (Scheme 1) [a,b].

![Scheme 1 Preparation of 1a–4a with bidentate N°N donors: 4,4'-dimethyl-2,2'-bipyridine (1a), 4,4'-di-i-t-butyl-2,2'-bipyridine (2a), 2,2'-bipyrazine (3a) and 2,2'-bipyrimidine (4a). Preparation of 5a–10a, 1b and 1f using L: pyrazole (5a), 4-methyl-pyrazole (6a), indazole (7a), imidazole (8a), benzimidazole (9a), quinazoline (10a), pyridine (1b) and 4-cyano-pyridine (1f).]

From the mononuclear complexes 1a–10a, 1b and 1f a preference for the trans configuration of the N-donor ligands to the methyl ligands and mutual trans coordination of the bromo ligands is apparent. While the reactivity of [(PtBr₂Me₂)ₙ] with various donor ligands has been described here the range and nature of the N-heterocyclic donor ligands has been extended.²⁷

Proton exchange on the pyrazole ligand

It was found that the proton bound to C⁴ on the coordinated pyrazole ligands of [PtBr₂Me₂(H-pz)₂] (5a) is completely substituted (spectroscopic yield 100%) in a methanol-d4 solution by a deuteron (Scheme 2). While the N¹–H proton is substituted in free and coordinated pyrazole in CD₃OD, no observable deuteration of the C⁴ hydrogen was noted for the free ligand in CD₃OD. Increased reactivity at the C⁴ position of coordinated pyrazole ligands has also been observed for other complexes with pyrazole ligands.²⁸ Substitution of 5a occurs faster in the presence of
Results and Discussion

$[\text{PtBr}_2\text{Me}_2(\text{CD}_3\text{OD})_2]$, indicating that intermediately formed $[\text{PtBr}_2\text{Me}_2(\text{CD}_3\text{OD})(\text{H-pz})]$ may increase the reactivity at the C$^4$ position.

Scheme 2  Tetradeuteration of the pyrazole ligands of 5a.

2.1.2. With $\alpha,\omega$-bis(azol-1-yl) alkanediyl ligands

Alkanediyl linked bis(phosphino) ligands can act as $\text{trans}$ spanning bidentate ligands.$^{29}$ Although alkanediyl bridged bis(pyrazol-1-yl) ligands have been reported for some time, investigations of their behavior as ligands is relatively limited.$^{30}$ Complexes 1e and 3e afforded from the reaction of L1e with $[(\text{PtBr}_2\text{Me}_2)_n]$ and $[(\text{PtMe}_2(\text{cod}))\text{I}_2]$, respectively, are in accord with the coordination modes of various other alkanediyl linked bis(pyrazol-1-yl) compounds (Scheme 3).$^{30c-g}$

Scheme 3  Platinum(IV) complexes 1e–3e with alkanediyl linked ligands L1e or L2e.

As with L1e, 1,8-bis(pyrazol-1-yl)$n$-octane (L2e) reacted with $[(\text{PtBr}_2\text{Me}_2)_n]$ to give $[\text{PtBr}_2\text{Me}_2\{\text{pz}(\text{CH}_2)_8\text{pz}\}]$ (2e). In addition, dichloroplatinum(II) and diiodoplatinum(II) complexes (1d, 4d and 8d) were prepared according to the conditions described in [d] (Scheme 4). Without X-ray crystal analysis or mass spectrometry it was not possible to determine the exact nuclearity of 4d.
Results and Discussion

Scheme 4 Preparation of dichloroplatinum(II) and diiodoplatinum(II) complexes 1d, 4d and 8d.

2.1.3. With bis[2-(azol-1-yl)ethyl] ether/thioether ligands

Synthesis

The bis[2-(benzimidazol-1-yl)ethyl] ether ligand L9c reacted with [(PtBr₂Me₂)ₙ] to afford 9c (Scheme 5).

Scheme 5 Preparation of 9c with bis[2-(benzimidazol-1-yl)ethyl] ether L9c.

The reaction of bis[2-(pyrazol-1-yl)ethyl] ether/thioether (L3e/L4e) with platinum(IV) precursors is described in [e] (Scheme 6).

Scheme 6 Preparation of 4e and 5e with bis[2-(pyrazol-1-yl)ethyl] ether/thioether compounds.
The preparation of 4e and 5e shows the ease with which the neutral tridentate \( \kappa^{2}N,N',\kappa O \) or \( \kappa^{2}N,N',\kappa S \) donor set can coordinate to platinum(IV). Bis[2-(3,5-dialkylpyrazol-1-yl)ethyl] ether analogues of L3e have also been found to adopt versatile coordination modes.\(^{31}\) However, structures with neutral tridentate \( \kappa^{2}N,N',\kappa O \) ligands in platinum(IV) complexes or any hexacoordinated d-block element are unknown. Thus the solid state structure of 4e with a facial coordination of the tridentate ligand L3e is of interest. As was found for selected bis(azol-1-yl) complexes 1d, 4d and 8d (Scheme 4) above, diethyl ether linked derivatives of the bis(pyrazol-1-yl) and bis(imidazol-1-yl) ligands also reacted with K\(_{2}\)[PtCl\(_{4}\)] and K\(_{2}\)[PtI\(_{6}\)] to yield the respective platinum(II) complexes (Scheme 7).

**Scheme 7** Preparation of dichloroplatinum(II) and diiodoplatinum(II) complexes 2d, 5d and 9d.

**Linkage isomers**

Bis[2-(pyrazol-1-yl)ethyl] ether and longer polyether chained derivatives of L3e reacted with [(PtBr\(_{2}\)Me\(_{2}\))\(_{n}\)] to yield yellow oily residues that were difficult to characterize owing to a broadening of all resonances in the \(^{1}H\), \(^{13}C\) and \(^{195}Pt\) NMR spectra. This is in contrast to spectra of complexes 1c–13c. An equilibrium between the possible bidentate coordination modes of L3e, namely \( \kappa N,\kappa O \) or \( \kappa^{2}N,N' \) coordination, would be expected to result in broadening of both methyl and L3e resonances if the equilibrium was sufficiently slow on an NMR timescale (Scheme 8). The formation of other species in solution yielded from a bridging rather than chelating mode of the ligand may also cause broadening, as discussed for 7c and 12c below. However low temperature \(^{1}H\) NMR of solutions of L3e with [(PtBr\(_{2}\)Me\(_{2}\))\(_{n}\)] did not reveal signal coalescence and the shortness of the flexible spacer in L3e as
well as the $\kappa^2 N,N',\kappa O$ coordination mode of $\text{L3e}$ in 4e supports the formation of linkage isomers as a cause for broadening in the NMR spectra. Structurally similar ligands have also demonstrated the capacity of the ethereal oxygen atom to ligate.\textsuperscript{4d,31}

![Scheme 8](image)

**Scheme 8** Possible equilibrium between linkage isomers with the $\text{L3e}$ ligand.

### 2.1.4 With $\alpha,\omega$-bis(imidazol-1-yl) or $\alpha,\omega$-bis(benzimidazol-1-yl) polyether ligands

**Synthesis**

The preparation of platinum(IV) metallacrown ethers using either $\alpha,\omega$-bis(imidazol-1-yl) or $\alpha,\omega$-bis(benzimidazol-1-yl) compounds was readily accomplished under mild reaction conditions (Scheme 9) [c].

![Scheme 9](image)

**Scheme 9** The preparation of platinum(IV) complexes with (i) $\alpha,\omega$-bis(imidazol-1-yl) and (ii) $\alpha,\omega$-bis(benzimidazol-1-yl) polyether ligands.

This series of complexes represents a new family of metallacrown ethers bearing $\alpha,\omega$-bis(azol-1-yl) polyether ligands rather than the more commonly employed $\alpha,\omega$-bis(phosphino) polyether ligands. The $\alpha,\omega$-bis(imidazol-1-yl) polyether $\text{L3c}$ also reacted in a fashion similar to $\text{L1e}$ described above (section 2.1.2.) to yield the diiodo complex 13c (Scheme 10).
Results and Discussion

Platinum(II) metallacrown ether complexes bearing $\alpha,\omega$-bis(phosphino) polyether ligands have been described, although their complexation chemistry with Li$^+$ and Na$^+$ is not straightforward. As with 1d, 2d, 4d and 5d the preparation of dichloroplatinum(II) complexes with bis(azol-1-yl) polyether ligands was accomplished under mild reaction conditions (Scheme 11) [d].

$\alpha,\omega$-Bis(pyrazol-1-yl) polyether compounds with $x = 3$ to 5 ethyleneoxy groups on the polyether backbone were found to react with K$_2$[PtCl$_4$] yielding oily residues. These residues appear to be a mixture of two major and a number of minor unidentified products ($^1$H NMR spectroscopy). The preparation of larger platinum(II) metallacrown ethers would be necessary to examine the host properties of these complexes since fewer than four ethyleneoxy groups are not expected to be sufficient for complexation in the metallacrown ether cavity.

Additionally it was also found that the $\alpha,\omega$-bis(imidazol-1-yl) polyether compounds with more than three ethyleneoxy groups did not react with K$_2$[PtCl$_4$], while none of the $\alpha,\omega$-bis(imidazol-1-yl) compounds were found to react with K$_2$[PtI$_6$] under the conditions that yielded 8d and 9d. The reasons for this unexpected inertness of the respective $\alpha,\omega$-bis(imidazol-1-yl) polyether compounds with K$_2$[PtCl$_4$] and K$_2$[PtI$_6$] is not clear, particularly since the $\alpha,\omega$-bis(pyrazol-1-yl) derivatives behave differently.

\[ \text{Scheme 10 Preparation of 13c from [PtMe}_2\text{(cod)}]/\text{I}_2 \text{ and L3c.} \]
Monomer/dimer(oligomer) equilibrium in solution

In solutions of 7c and 12c a second set of resonances was observed in the $^1$H, $^{13}$C and $^{195}$Pt NMR spectra as the concentration of the solution was increased above ca. 0.04 mol/l. This behavior was not observed at similar concentrations in solutions of the smaller metallacrown ethers. Increasing the concentration of a solution of either 7c or 12c above ca. 0.04 mol/l increased the intensity of the second set of resonances (Fig. 6). The formation of trans spanning isomers, as was found for Pd(II) metallacrown ethers having $\alpha,\omega$-bis(phosphino) polyether ligands,\textsuperscript{32} is considerably unlikely for the hexacoordinated complexes of 7c and 12c due to the steric requirements of the platinum coordination sphere and aromatic ligating imidazol-1-yl and benzimidazol-1-yl moieties.

![Partial $^1$H spectrum of 7c in CDCl$_3$ showing the Pt–CH$_3$ singlet with $^{195}$Pt satellites in solutions of ca. 0.24 mol/l (top), 0.08 mol/l (middle) and 0.04 mol/l (bottom).](image)

In addition, if trans isomers were formed a distinctly different set of resonances may be expected in the methyl region of the $^1$H NMR spectrum (i.e. methyl ligand trans configured to methyl ligand would result in a substantial decrease in $^2$J$_{PL,H}$ coupling). However this is not found to be the case and the configuration at the platinum atom is the same for both species (methyl ligand trans configured to nitrogen donor ligands). Thus, this concentration dependent equilibrium is attributed to the formation of oligomeric, probably dimeric, species in solution (Scheme 12). In addition, the similarity of the species in solution is apparent from the relatively few changes in the respective $^1$H or $^{13}$C NMR spectra.
Results and Discussion

Scheme 12 Monomer and dimer concentration dependent equilibrium of 7c.

Metallacrown ether binding studies

The complexation chemistry of dialkylammonium salts has undergone renewed attention over the last number of years owing to the interesting pseudo-rotaxane and rotaxane structures yielded in combination with crown ether cavities of suitable dimensions. Starting with metallacrown ether 5c (21-membered cavity ring) the complexation of di-n-butylammonium and dibenzylammonium hexafluorophosphate salts was investigated (Fig. 7a,b). Binding studies with these ammonium salts were conducted mostly in methylene chloride (studies with 11 in chloroform). In more polar solvents such as acetonitrile and acetone no evidence of any interaction was observed, indicating the relative strength of the interaction between the ammonium ions and the metallacrown ethers.

Fig. 7 Complexes (a) and diorganyl ammonium salts (b) used in the binding studies.

Evidence of an interaction between the metallacrown ethers and the ammonium ions was apparent from the respective NMR spectra and was supported by NOE experiments and HR-ESI-MS investigations. In addition, the metallacrown ethers (5c–7c, 11c and 12c) significantly enhanced the solubility of the respective ammonium salts. Furthermore, mixing of 7 and [Bu₂NH₂][PF₆] at room temperature revealed that the complexation-decomplexation equilibrium was reached quickly on a
Results and Discussion

Although the resonances of the ethereal backbone experience only very slight changes in shift on binding, these signals are generally broadened and increased in complexity. Broadening of resonances is observed in other binding studies and is largely attributed to rapid complexation-decomplexation of the host-guest species on an NMR timescale or a decrease in the longitudinal relaxation time ($T_1$) of the molecule.\(^\text{33}\) However, variable temperature NMR experiments with selected metallacrown ether/ammonium salt combinations did not reveal coalescence (cooling down the sample) or narrowing (heating up the sample) of the broadened resonances within the temperature range possible with the solvent ($\text{CD}_2\text{Cl}_2$ mp. –97 °C; bp. 39.8 °C).

In addition to the broadening of the signals, only a slight complexation induced shift was observed for what appears to be a rapid exchange on an NMR timescale and determination of binding constants was not possible. The exception to this behavior was slow exchange observed for complexation between 12c and the dibenzylammonium ion. Determination by single point methods disclosed a relatively weak binding constant ($K_a = 5$ l/mol in $\text{CD}_2\text{Cl}_2$ at 27 °C). Although no numerical value was established, Bélanger et al. also reported weak binding between their rhenium metallacrown ether and the ammonium ion.\(^\text{6e}\)

The type of interaction, a face-to-face or a threading of the macroring by the ammonium ion can only be speculated in the absence of solid state structure analysis (Fig. 8).

However the cavity of the metallacrown ethers are of comparable ring size (21-membered and greater) to crown ethers that have been used as host molecules in pseudo-rotaxane interactions with these ammonium ions.\(^\text{10a,b}\) While the improved
Results and Discussion

Solubility of the ammonium salts and ESI-MS spectra indicate a 1:1 interaction in all cases, NOE experiments may hint at the type of interactions. NOE experiments involved irradiation of the proton resonances of the polyether backbone on the metallacrown ether. The resulting spectra were examined for intensity enhancement of the resonance attributed to the \(\alpha\)-protons of the ammonium ion \([\text{(RC}^\alpha\text{H}_2\text{)}_2\text{NH}_2]^+\).

From the NOE experiments it was found that the smaller metallacrown ethers of each series (5c and 11c) did not give any intensity enhancement of the \(\text{C}^\alpha\text{H}_2\) resonance of the dibenzylammonium ion. In addition, no intensity enhancement was found for the \(\text{C}^\alpha\text{H}_2\) resonance of the di-\(n\)-butylammonium ion in solution with 11c. The lack of intensity enhancement for the various experiments with 5c and 11c may be interpreted as an indication of an interaction differing from those of the larger metallacrown ethers (6c, 7c and 12c) where intensity enhancements were observed. The pseudo-rotaxane interactions resulting from the threading of dialkylammonium ions with crown ethers of generally 24-membered (or greater) rings is well investigated, while smaller crown ethers facilitate a face-to-face interaction.\(^{10,34}\) It is therefore quite possible that 5c, a 21-membered metallacrown ether, may be too small to allow threading of the larger ammonium ion, if perhaps even the less bulkier di-\(n\)-butylammonium ion. The larger macrorings of 6c and 11c (24-memebered) and 7c and 12c (30-memebered) are of sufficient size in this respect to facilitate threading. It may also be expected that the bulkier benzimidazol-1-yl moiety may increase crowding at the cavity of the metallacrown ether and thereby prevent threading of the dibenzylammonium ion through the cavity of 11c. Thus a face-to-face type interaction may result and remove the \(\text{C}^\alpha\text{H}_2\) protons from the vicinity of the metallacrown ether ring protons, thereby causing no intensity enhancement in the NOE experiments.

2.1.5. With phosphino ligands

By analogy to a procedure using similar ligands and \([\text{PtCl}_2(\text{cod})]^{4d}\), 1,8-bis(diphenylphosphino)-3,6-dioxaoctane (dpdo) was reacted with \([\text{PtCl}_2(\text{nbd})]\) to yield \([\text{PtCl}_2(\text{dpdo})]^{(3f)}\), a known complex previously isolated from a refluxing reaction mixture of dpdo with \(\text{K}_2[\text{PtCl}_4]\) (Scheme 13 and appendix 2).\(^{35}\) The reaction of dpdo with \([(\text{PtBr}_2\text{Me}_2)_n]\) yields mixtures of inseparable products, probably due to reductive
elimination reactions.\textsuperscript{36} Similarly, several products were observed (\textsuperscript{1}H NMR) in the reaction of triphenylphosphine with \([\text{[PtBr}_2\text{Me}_2)_n]\) (Scheme 14 and appendix 2).

\[
\text{[PtCl}_2\text{(nbd)] + Ph}_2\text{P} - \text{O} - \text{O} - \text{PPh}_2 \xrightarrow{\text{CH}_2\text{Cl}_2, \text{rt, 30 min}} \begin{array}{c}
\text{Cl} \\
\text{Ph}_2\text{Ph}
\end{array}
\]

**Scheme 13** Preparation of 3f from \([\text{PtCl}_2\text{(nbd)]}\) and dpdo.

\[
\text{[PtBr}_2\text{Me}_2)_n] + 2 \text{PPh}_3 \rightarrow \begin{array}{c}
\text{Br} \\
\text{Pt} \\
\text{PPh}_3 \\
\text{PPh}_3 \\
\end{array} + \text{other products of reductive elimination}
\]

**Scheme 14** Preparation of 4f from PPh\textsubscript{3} and \([\text{PtBr}_2\text{Me}_2)_n]\).

One of these products, cis-\([PtBr}_2\text{(PPh}_3)_2\) \(4f\) is insoluble in benzene and was isolated from the reaction mixture by filtration. Both cis- and trans-\([PtBr}_2\text{(PPh}_3)_2\) are known in the literature, although the X-ray crystal structure analysis of cis-\([PtBr}_2\text{(PPh}_3)_2\] is not described (Fig. 9 and appendix 2).\textsuperscript{37}

\[\text{Fig. 9} \text{ Molecular structure of cis-[PtBr}_2\text{(PPh}_3)_2], \text{CHCl}_3, \text{CHCl}_3 \text{ and hydrogen atoms omitted for clarity. Displacement ellipsoids at } 30\% \text{ probability.}\]

Resonances in the \textsuperscript{1}H NMR attributed to alkanes, mainly ethane and propane, were also among the products of the reaction between triphenylphosphine and \([\text{[PtBr}_2\text{Me}_2)_n]\). These alkanes are consistent with reductive elimination of the methyl ligands from platinum(IV), a process observed for many other platinum(IV) complexes with alkyl and phosphine ligands.\textsuperscript{36}
2.2. Platinum(IV) complexes of higher nuclearity

2.2.1. Strategies for dinuclear complexes

The dinuclear complexes obtained herein were prepared by two main strategies. The first involved the use of $N$-heteroaromatic ligands that can present at least two ligating nitrogen donor atoms. Deprotonation of the pyrazole ligand of 5a allowed coordination through the second nitrogen atom of this $N$-heteroaromatic ligand. Other ligands such as 2,2'-bipyrimidine and 4,4'-bipyridine present a second set of nitrogen donors without deprotonation. With these $N$-heteroaromatic ligands the bridging moiety is rigid owing to the aromaticity of the bridging entity. In addition the metal centers are in relative close proximity (11a: Pt····Pt 3.593(1) Å).

The second strategy involved the use of ligands with flexible spacers such as 1,2-bis(benzimidazol-1-yl)ethane (L8). Although connected by a flexible ethylene or, as was the case for 2c, diethyl ether spacer, the formation of a complex with a chelating mode of the respective ligand is disfavored due to the relative positioning of the nitrogen donors on the bis(azol-1-yl) moieties. Hence the difference in coordination mode between 1,2-bis(pyrazol-1-yl)ethane a chelating ligand in 1e, and L8, a bridging ligand in [(PtBr$_2$Me$_2$)$_2$(μ-bimCH$_2$CH$_2$bim)$_2$] (8c). The distance between the platinum atoms in the resulting dinuclear complexes is increased relative to the dinuclear complexes obtained by the strategy described above, (8c: Pt····Pt 9.4730(4) Å). As the length of the chain increases between the bis(azol-1-yl) moieties the chelate effect prevails, as may be expected.

Collectively both strategies belong to the so-called “molecular library” model applied in the self-assembly of metallamacrocycles.  

2.2.2. With $N$-heteroaromatic donors

Bridging pyrazolato

Deprotonation of the $N$-heterocyclic ligands of 5a, [PtBr$_2$Me$_2$(4-Me-H-pz)$_2$] (6a), [PtBr$_2$Me$_2$(H-im)$_2$] (8a) and [PtBr$_2$Me$_2$(H-bim)$_2$] (9a) was expected to lead to a second ligating nitrogen donor site free to facilitate a bridging coordination mode of the respective ligand. A number of structures with bridging pyrazolato ligands between two group 8–10 organometallic fragments are known. Bridging modes of imidazolato moieties, particularly of dibenzimidazolato ligands, in the construction of multinuclear complexes are also of interest owing, among other features, to their
Results and Discussion

electronic coupling properties between two metal atoms.\textsuperscript{40} Deprotonation of 5a allowed the formation of the dinuclear complex [PPh\textsubscript{4}][(PtBrMe\textsubscript{2})\textsubscript{2}(\mu-Br)(\mu-pz)\textsubscript{2}] (11a) (Scheme 15).

\begin{center}
\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{scheme15.png}
\caption{Scheme 15 Preparation of 11a from 5a.}
\end{figure}
\end{center}

Similar reactions with 6a, 8a and 9a gave multiple products that could not be separated. The bridging mode of the pyrazolato ligand of 11a was anticipated since although chelating pyrazolato ligands are known,\textsuperscript{41} dinuclear complexes with bridging pyrazolato ligands are extremely prevalent.\textsuperscript{39,42} The stability of 11a was demonstrated by its inertness towards substitution of the bridging bromo ligand in the presence of silver salts, a reaction found to be successful for similar dinuclear platinum(IV) complexes with bridging iodo ligands.\textsuperscript{42}

\textit{Bridging 2,2'-bipyrimidine}

Bridging modes of bipyrimidine ligands have been shown to yield dinuclear complexes, of which only a small proportion have been characterized in solution.\textsuperscript{43,44} Mononuclear [PtBr\textsubscript{2}Me\textsubscript{2}(bpym)] (4a) was used as a starting complex for the preparation of [(PtBr\textsubscript{2}Me\textsubscript{2})\textsubscript{2}(\mu-bpym)] (12a) (Scheme 16).

\begin{center}
\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{scheme16.png}
\caption{Scheme 16 Preparation of dinuclear 12a from 4a.}
\end{figure}
\end{center}

Complex 12a dissolves only slowly in DMF (donor number (D. N.) = 26.6)\textsuperscript{45} and in doing so yields mononuclear 4a and [PtBr\textsubscript{2}Me\textsubscript{2}(DMF)\textsubscript{2}] in an equilibrium process. The stability of mononuclear 4a may act as a driving force in this process since only 4a is present in solution (\textsuperscript{1}H NMR) after one month, presumably accompanied by
Results and Discussion

degradation of 12a and [PtBr₂Me₂(DMF)]₂. Similar sets of signals were observed when DMSO (D. N. = 29.8) was used as the solvent system but the spectrum of 12a in weaker donor solvents such as THF (D. N. = 20) is featureless, indicating the relative stability of the bridging bipyrimidine complex.

4,4'-Bipyridine – possible tetracolumn complex

The product of the reaction between 4,4'-bipyridine and the [(PtBr₂Me₂)ₙ] precursor, [[PtBr₂Me₂(4,4'-bipy)]ₙ] (5f), demonstrates a 4,4'-bipyridine ligand to PtBr₂Me₂ ratio of 1 by NMR spectroscopy (¹H and ¹³C) and microanalysis. Furthermore, NMR spectroscopy is in accord with the presence of one platinum species (δPt –2343 ppm) and, from ¹H and ¹³C NMR spectroscopy, the coordination of both nitrogen donors of the ligand in identical surroundings. The formation of the molecular square [[PtBr₂Me₂(4,4'-bipy)]ₙ] although not proved conclusively, agrees with these results (Scheme 17). Mass spectrometry and X-ray crystal diffraction were not possible and thus the formation of polymeric entities cannot be ruled out, although a molecular square satisfies geometrical and thermodynamic considerations. The linear 4,4'-bipyridine ligand has been shown to form molecular squares with metal ion fragments meeting the correct geometrical requirements.⁴⁶ In contrast to this reaction with 4,4'-bipyridine, the linear ligand 4-cyano-pyridine, also an appropriate ligand for self-assembly of molecular squares,⁴⁷ yielded only the mononuclear complex [PtBr₂Me₂(4-CN-py)] (1f) (Scheme 17 and appendix 1).

**Scheme 17** The reaction yielding 1f and the proposed product of the reaction between 4,4'-bipyridine and [(PtBr₂Me₂)ₙ].
2.2.3. With bis(azol-1-yl) ligands

As discussed above bis(imidazol-4-yl) and bis(benzimidazol-4-yl) polyether compounds in combination with [(PtBr₂Me₂)ₙ] yielded mononuclear platinum(IV) metallacrown ethers. Compounds L₁c, L₂c and L₈c reacted with [(PtBr₂Me₂)ₙ] to yield dinuclear complexes (Scheme 18). Unlike the rigid N-heterocyclic bridging ligands described in the previous section above, these bis(azol-1-yl) ligands are relatively flexible due to the spacer between the azol-1-yl groups. This in turn reduces the directionality of the ligand and the orientation of the vacant coordination sites at the platinum atom becomes the principal source of directionality.

![Scheme 18](image-url)

**Scheme 18** The preparation of dinuclear platinum(IV) complexes with bis(imidazol-1-yl) and bis(benzimidazol-1-yl) ligands. Imidazol-1-yl: im. Benzimidazol-1-yl: bim.

The two ethylene-bridged complexes [(PtBr₂Me₂)₂(μ-L₁c)₂] (1c) and [(PtBr₂Me₂)₂(μ-L₉c)₂] (9c) are assigned as dinuclear. Since 9c is completely insoluble characterization of 9c is eluded from its solid state structure and microanalysis only. Although 1c was of sufficient solubility to allow NMR spectroscopy, determinative assignment via mass spectrometry or X-ray crystal diffraction analyses was not possible. Nevertheless, due to the structural similarities of the ligands L₁c and L₈c and the known propensity of L₁c to adopt bridging rather than chelating coordination modes,¹⁸ 1c is more than likely dinuclear.

It was somewhat unexpected that [(PtBr₂Me₂)₂(μ-L₂c)₂] (2c) was dinuclear since the analogous benzimidazolyl ligand L₉c yielded the mononuclear complex [PtBr₂Me₂(L₉c)] (9c) under the same reaction conditions. In addition, X-ray crystal
structure analysis of the platinum(II) complex \([\text{PtCl}_2(\text{L}5\text{d/L}2\text{c})] (5\text{d})\) (Section 2.1.3.) shows that the ligand can chelate in a bidentate fashion. The reason for the bridging mode of \(L2\text{c}\) in \(2\text{c}\) is not clear since the bulkier ligating benzimidazolys of \(L9\text{c}\) were expected to be the most likely of the two analogues \(L2\text{c}\) and \(L9\text{c}\) to yield a dinuclear complex with \([\text{PtBr}_2\text{Me}_2]_2\). Complexes \(2\text{c}\) and \(9\text{c}\) have distinctly different solubilities. While \(9\text{c}\) has some solubility in the CHCl\(_3\) (reaction solvent) and CH\(_2\)Cl\(_2\), \(2\text{c}\) appears completely insoluble in both solvents. If we assume an equilibrium process between mononuclear and dinuclear species in each reaction it may be that \(2\text{c}\) and \(9\text{c}\) are the least soluble species from each respective pair and the equilibria shift accordingly to the least soluble product.

### 2.3. Spectroscopic and structural investigations

#### 2.3.1. Spectroscopic data

Where solubility allowed all complexes isolated during the course of these investigations were characterized by NMR spectroscopy (\(^1\text{H}, \, ^{13}\text{C}\) and \(^{195}\text{Pt}\)). The \(^1\text{H}\) NMR spectra of the dimethyl and trimethyl platinum(IV) complexes \(1\text{a}–12\text{a}, \, 1\text{c}–13\text{c}, \, 1\text{e}–5\text{e}, \, 1\text{f}, \, 2\text{f}\) and \(5\text{f}\) showed a singlet plus doublet resonance pattern shifted between 0.95–2.66 ppm assignable to the methyl ligands (Table 1).

\(a\) \(N\)-donor of bridging pyrazolato. \(b\) \(N\)-donor of bridging bipyrimidine. \(c\) \(^{13}\text{C}\) NMR not possible. \(d\) Iodo ligands in axial position.
The $^2J_{\text{Pt,H}}$ coupling of the methyl protons range between 66.6 and 80.7 Hz, depending on the donor atom coordinated \textit{trans} to the methyl ligands. The $^{13}\text{C}$ NMR spectra of the same dimethyl and trimethyl platinum(IV) complexes showed a similar pattern assignable to the methyl ligands shifted in a range between –19.3 and 9.3 ppm. Where observed the $^1J_{\text{Pt,C}}$ coupling of the carbon atoms of the methyl ligands lie between 501.4 and 773.3 Hz again depending on the donor atom coordinated \textit{trans} to the methyl ligands. The $^{195}\text{Pt}$ NMR spectra of the complexes reported in a–f show that all values fall in a relatively narrow range regardless of the oxidation state (−1991 to –3409 ppm). This narrow range of values is consistent with those found in the literature for similar platinum(II) and platinum(IV) complex types.\textsuperscript{27a,49} High-field chemical shifts of complexes with iodo rather than bromo ligands (3c/13c $\delta_{\text{Pt}}$–2362/–2738 ppm and 1e/3e –2319/–3409 ppm) are consistent with the trend observed for platinum complexes of many types where bromo ligands are substituted by iodo ligands.\textsuperscript{49a}

2.3.2. Structural investigations

\textit{Structure types}

Single crystals of several of the complexes from these investigations reported in [a–e] were characterized by X-ray crystal diffraction. These complexes can be grouped according to the respective donor sets around the central platinum atom, namely [Br$_2$C$_2$N$_2$], [C$_3$N$_2$O], [Br(µ-Br)C$_2$(µ-N)$_2$] and [Cl$_2$N$_2$]. The structures of the platinum(IV) complexes show a roughly octahedral arrangement of the ligating atoms around the central platinum atom, with the nitrogen donor ligands configured \textit{trans} to the methyl ligands. Where bromo ligands are present these are configured mutually \textit{trans} to one another. The vast majority of the structures discussed in [a–e] have the dibromodimethylplatinum(IV) entity and collectively represent the most substantial body of structural data related to this moiety.\textsuperscript{50} Structures of 5d and 6d show a square planar arrangement of the ligating atoms around the platinum(II) atom. The individual features of the solid state structures are discussed in the relevant reference [a–f].
Weak interactions in the solid state

Collectively, a number of intermolecular and intramolecular interactions are observed within the crystal structures. A prevalent intramolecular and intermolecular interaction found is the weak hydrogen bond (<16 kJ/mol). These hydrogen bonding interactions are characterized by three main parameters: (i) the distance between the donor-acceptor pair, (ii) the distance between the hydrogen atom and the acceptor and (iii) the donor-hydrogen atom-acceptor angle. Table 2 collects some of the (i) and (iii) parameters found for the intramolecular hydrogen bonding interactions of 5a, 6a, 1b, 6d and 1f and the intermolecular hydrogen bonding and interionic hydrogen bonding interactions found for 7a and 4e, respectively.

*Positions of hydrogen atoms calculated and angle estimated from these positions.

Most weak hydrogen bonding interactions present in the structures (exception 4e and 7a) were found between the hydrogen atom on the aromatic carbon/nitrogen atom (donor) neighboring the ligating nitrogen atom ("C/"N) and halo ligands of the same molecule (acceptors). The range of angles and lengths typically found in structures believed to exhibit these interactions in complexes with acceptor halo ligands has been reviewed. In all structures reported in [a–f] where hydrogen bonding is observed the hydrogen atoms were added to the structures using the 'Riding Model' and thus the distance between the hydrogen atom and acceptor atom and the angle given by donor-hydrogen atom-acceptor atoms must not be overestimated. However,
a donor-acceptor distance less than the sum of the van der Waals radii ($R_{\text{donor,acceptor}}$) is taken as a strong indicator of hydrogen bonding in these complexes (van der Waals radi: $R_{\text{CBr}} = 3.55 \, \text{Å}$; $R_{\text{NBr}} = 3.40 \, \text{Å}$; $R_{\text{CCl}} = 3.45 \, \text{Å}$; $R_{\text{CF}} = 3.17 \, \text{Å}$).

In addition to weak hydrogen bonding interactions involving Br, Cl and F acceptors, aromatic-aromatic interactions ($<$15 kJ/mol) are also present in many of the solid state structures reported in [a–e]. These interactions are divided into three main types depending on the geometry of the interaction: edge-face, offset stacked and face-to-face (Fig. 12a–c). Such interactions are ubiquitous in nature and have been utilized by chemists in the assembly of supramolecular entities. Although there is ongoing discussion as to the contribution of each, aromatic-aromatic interactions consist of van der Waals, hydrophobic and electrostatic forces. Since $\pi$-deficient-$\pi$-deficient aromatic systems have been shown to be more stable than $\pi$-deficient-$\pi$-rich and $\pi$-rich-$\pi$-rich systems, heterocyclic nitrogen ligands are favorable systems for $\pi-\pi$ interactions due to their low $\pi$-electron density. The geometrical parameters indicating offset stacked and face-to-face interactions are given by the distance between two parallel ring systems, the distance between their centroids and the displacement angle. Several of the solid state structures reported in [a–d] demonstrate interactions corresponding to the more stable (minimized $\pi$ electron repulsion and maximized $\sigma$ framework attraction to the $\pi$ electron density) offset stacked arrangement, as is apparent from the parameters in Table 3. These parameters are consistent with the findings of other studies reporting such interactions.

2.4. Anticancer evaluation

Structure-activity relationship

As described in [c] the *in vitro* antitumor activity of selected compounds from the series 1c–13c was assessed on the tumor cell lines lipocarcoma, A549 (non-small-cell lung carcinoma) and 518A2 (melanoma). The compounds investigated by cytotoxicity assay were selected with the aim of examining the structure-activity relationship (Fig. 11).

![Complexes tested for anticancer activity](image)

**Fig. 11** Complexes tested for anticancer activity.
Free ligands \textbf{L1c} (imCH\textsubscript{2}CH\textsubscript{2}im) and \textbf{L6c} (imCH\textsubscript{2}CH\textsubscript{2}(OCH\textsubscript{2}CH\textsubscript{2})\textsubscript{5}im) and the solvated starting complex [PtBr\textsubscript{2}Me\textsubscript{2}(DMF)\textsubscript{2}] were included as indicators of the activity of the individual moieties of the corresponding complexes. Table 4 shows a summary of the cytotoxicity data where the IC\textsubscript{50} represents the dose required to reduce the number of living cells by 50%.

Table 4 IC\textsubscript{50} values [\mu M] from the cytotoxicity assay on liposarcoma, A549 (lung carcinoma) and 518A2 (melanoma). Evaluation of cisplatin is under similar conditions. \(x\) = number of ethyleneoxy groups [c].

Although \textbf{L6c} exceeded the measurement range, \textbf{L1c} showed a measure of activity similar to that of its corresponding platinum(IV) complex. It is known that simple substituted \(N\)-heterocyclic compounds such as \textbf{L1c} can act as activators of carbonic anhydrases.\textsuperscript{55} Carbonic anhydrases (CA) are a family of zinc(II) isoenzymes responsible for the catalytic conversion of carbon dioxide to bicarbonate ions and are found in many tissues and organs in humans (\(\alpha\)-CA).\textsuperscript{56} Some of these isoenzymes, for example CA IX and CA XII, are overexpressed in many tumors and lead to acidification of the tumor tissue.\textsuperscript{57} Although \textit{in vitro} experiments do not simulate the hypoxia conditions found in tumor tissue it is nevertheless of interest to note the moderate activity of \textbf{L1c}, a carbonic anhydrase activator, and its corresponding complex \textbf{1c}. In general, the higher activity of all complexes relative to the solvated...
starting complex indicates only that the activity is improved by the polyether ligands, possibly due to the more inert nature of the polyether ligands relative to the DMF ligand.

Although investigations on the mode of action of platinum(IV) anticancer complexes such as satraplatin are ongoing, reduction and reduction rates are of interest since the active species can be platinum(II) metabolites.\(^\text{19}\) If platinum(II) metabolites are the active species derived from the platinum(IV) complexes tested in \([\text{c}]\) (\(1\text{c}–13\text{c}\)), then reductive elimination of both axial ligands (halide), both methyl ligands or a halide and a methyl ligand may generate the active species. Replacing the bromo ligands with iodo ligands (\(3\text{c}→13\text{c}\)) or the introduction of benzimidazol-1-yl rather than imidazol-1-yl moieties (\(3\text{c}→11\text{c}\)) did not appear to influence the activity substantially. Increasing the number of ethyleneoxy units on the ligand backbone from two to five (\(3\text{c}→6\text{c}\)) caused little change in the cytotoxicity on any of the cell lines. Nevertheless, these complexes are examples of active dibromo (\(2\text{c}, 3\text{c}, 6\text{c} \text{ and } 10\text{c}\))/diiodo (\(13\text{c}\)) platinum(IV) complexes, both of which are much less reported than the traditional anticancer platinum complexes with chloro ligands.\(^\text{19b,58}\) Furthermore, reports on the anticancer properties of compounds with platinum-carbon bonds are scarce in the literature and this series expands on the small number already reported.\(^\text{19a,42,59}\)

**Cell death**

Platinum drugs can induce one of two modes of cell death, apoptosis (programmed cell death) or necrosis (accidental cell death). Trypan-blue staining tests demonstrate that apoptosis is induced preferentially by the complexes \(1\text{c}–3\text{c}, 6\text{c}, 10\text{c} \text{ and } 13\text{c}\). The test is a primary indicator of cell death and further tests are required to confirm the induced mode of cell death. Nonetheless, breakdown of the cell membrane is an indicator of necrosis and exclusion of the dye for a significant period of time in the presence of cytotoxic quantities of the drugs is consistent with apoptosis. In addition it was noted that the melanoma cell line 518A2 was sensitive to the dibromo bis(imidazolyl) complexes \(1\text{c}–3\text{c} \text{ and } 6\text{c}\), as observed by the quick onset of secondary necrosis.
Results and Discussion

Platinum-uptake

Platinum-uptake is a quantitative measure of the amount of platinum entering the cell. This is of interest since uptake may be correlated with cytotoxicity. The platinum-uptake of 1c–3c, 6c, 10c and 13c showed little evidence of any correlation with cytotoxicity. The uptake of most compounds was higher than cisplatin on cell lines A549 and 518A2, while uptake in liposarcoma was higher than cisplatin for 1c, 10c and 13c only. It has been shown in vitro that platinum(IV) complexes often demonstrate significantly better lipophilicity than commercial platinum(II) drugs.21 Such platinum(IV) complexes can effectively cross the cell membrane by passive diffusion and consequently an increased accumulation of platinum can be observed in the cells. This may also be the reason for the drastic increase in platinum-uptake observe for 1c relative to the other polyether type complexes and cisplatin.

While at best the activity of the polyether complexes was ca. 40 times less than that of cisplatin the platinum(IV) complexes tested from the series 1c–13c, can still be regarded as moderately active on all three cell lines. There is in most cases no evidence of selectivity between the various tumor cell lines, as is evident from the IC50 values. The only exception to this lack of selectivity is the marginally better performance of 6c on the liposarcoma tumor cell line which is approximately twice as high as the activity found on the A549 and 518A2 cell lines.
3. Summary

The construction of supramolecular entities via the self-assembly approach has been an area of significant interest in recent years. With the growth of this area new classifications for metallasupramolecules have emerged including metal molecular polygons and metallacrown ethers. The search for improved metal based anticancer drugs continues to be a major area of research within inorganic chemistry. While initially focused on a relatively narrow range of platinum(II) complexes, interest in the anticancer properties of platinum(IV) complexes has intensified over the last 15 years owing to the small number of platinum(IV) complexes to have reached clinical trials. Within the scope of the work herein platinum(II)/(IV) complexes with a range of nitrogen donor ligands were prepared and characterized. These included both mononuclear and dinuclear species. Chief among the mononuclear complexes is a family of metallacrown ethers, inorganic analogues of crown ethers. Different properties including reactivity, binding propensity and anticancer behavior were evaluated for the complexes described herein. The overall results reported in this work may be summarized as follows:

1. The reaction of $[\text{PtBr}_2\text{Me}_2]_n$ (A) with N-heteroaromatic donors yielding $[\text{PtBr}_2\text{Me}_2(\text{N}^\infty\text{N})]$ (N$^\infty$N: bidentate N-donor ligand such as bipyrimidine; 1a–4a) and $[\text{PtBr}_2\text{Me}_2(L)_2]$ (L: N-heterocyclic monodentate ligand such as pyrazole; 5a–10a and 1f) type complexes proved a simple and efficient synthesis of dibromodimethylplatinum(IV) complexes with N-donors.

2. A number of platinum(II) complexes with alkanediyl, diethyl ether and polyether linked bis(azol-1-yl) ligands (azol-1-yl: pyrazol-1-yl (pz), imidazol-1-yl (im),
benzimidazol-1-yl (bim)) were also prepared. Reactions of ethylene or diethyl ether linked bis(pyrazol-1-yl) ligands with K₂[PtI₆] yielded [PtI₂{pz(CH₂CH₂O)xCH₂CH₂pz}] (x = 0, 8d; x = 1, 9d). A broad spectrum of compounds reacted with K₂[PtCl₄] to yield complexes of the generic type [PtCl₂(Y(CH₂CH₂O)xCH₂CH₂Y)] (Y: pyrazol-1-yl (1d–3d), imidazol-1-yl (4d–6d) or benzimidazol-1-yl (7d); x = 0–3; see scheme above). Although this series included 6d, a complex with a 16-membered ring, isolation of larger platinum(II) metallacrown ethers with these ligands requires further investigation since reactivity with the longer α,ω-bis(azol-1-yl) polyether compounds differs from that of the shorter chained compounds.

3. Bis(pyrazol-1-yl) compounds proved flexible bidentate and tridentate ligands in platinum(IV) complexes. 1,2-Bis(pyrazol-1-yl)ethane reacted with [PtMe₂(cod)]I₂ and [(PtBr₂Me₂)n] to yield platinum(IV) complexes with seven-membered chelate rings, [PtI₂Me₂(pzCH₂CH₂pz)] (3e) and 1e, respectively. 1,8-Bis(pyrazol-1-yl)-n-octane also reacted with [(PtBr₂Me₂)n] to yield [PtBr₂Me₂(pz(CH₂)₈pz)] (2e). Bis[2-(pyrazol-1-yl)ethyl] ether/thioether ligands reacted with [(PtMe₃)₄] in the presence of a silver salt (e.g. AgBF₄) to yield 4e and [PtMe₃(pzCH₂CH₂SCH₂CH₂pz)][CF₃SO₃] (5e), with κ²N,N',κO and κ²N,N',κS coordination, respectively. Thus, the bis(pyrazol-1-yl) compounds examined here facilitate the formation of platinum(IV) complexes with chelating bi- or tridentate modes of the ligand, depending on the requirements at the metal centre.

4. A range of α,ω-bis(azol-1-yl) polyether compounds (azol-1-yl: imidazol-1-yl or benzimidazol-1-yl) reacted with precursor A to afford a series of platinum(IV) metallacrown ethers (3c–7c and 9c–12c, see scheme above). In addition, a diiodo analogue of these metallacrown ethers, 13c, was prepared by combining [PtMe₂(cod)]I₂ with the appropriate α,ω-bis(imidazol-1-yl) ligand. These platinum(IV) metallacrown ethers represent a departure from the more common type of metallacrown ethers prepared with α,ω-bis(phosphino) polyether compounds.
Summary

5. The host properties of the larger members of this series of metallacrown ethers (5c–7c, 11c and 12c) were investigated with di-n-butylammonium and dibenzylammonium ion guests, respectively. NMR investigation, NOE experiments, HR-ESI-MS analysis and a visual enhancement in the solubility of the ammonium salts in chlorinated hydrocarbons verified the presence of host-guest interactions. Fast complexation-decomplexation equilibria and weak binding interactions predominate between these host/guest species in solution.

6. Starting from the mononuclear building blocks [PtBr₂Me₂(H-pz)₂] (5a) and [PtBr₂Me₂(bpym)] (4a) the dinuclear complexes [PPh₄][(PtBr₂Me₂)₂(µ-Br)(µ-pz)₂] (11a) and [(PtBr₂Me₂)₂(µ-bpym)] (12a) could be prepared and isolated.

α,ω-Bis(imidazol-1-yl/benzimidazol-1-yl) compounds with short ligand spacers resulted in dinuclear complexes in combination with [(PtBr₂Me₂)ₙ] (1c, 2c and 8c).

Although the steric requirements of the ethylene bridged ligands in 1c and 8c were expected to lead to dinuclear complexes, the formation of 2c was somewhat unexpected, particularly since the same α,ω-bis(imidazol-1-yl) ligand adopted a bidentate mode with a platinum(II) precursor (2d) and the α,ω-bis(benzimidazol-1-yl) derivative of this ligand was also bidentate in 9c.
7. The majority of the platinum(IV) complexes reported herein have a *trans* configuration of a methyl ligand to a nitrogen donor atom (Me–Pt–N). Thus a range of chemical shift and coupling data characteristic of these methyl resonances was observed for such an arrangement. A number of solid state structures were determined during these investigations and many of these were found to exhibit weak intra- and intermolecular interactions such as aromatic-aromatic interactions and weak hydrogen bonding involving mostly metal bound halo ligands as acceptors. The parameters associated with these interactions are consistent with those in the literature.

8. *In vitro* studies of the cancerostatic properties of selected members of the metallacrown ether series (1c–3c, 6c, 10c and 13c) showed that these organometallic platinum(IV) complexes possess moderate activity on liposarcoma, lung carcinoma (A549) and melanoma (518A2) tumor cell lines. Despite the structural variation of 3c (two versus five ethyleneoxy groups, 3c/6c; imidazolyl versus benzimidazolyl, 3c/10c; bromo versus iodo, 3c/13c) a clear relationship between either the structure of the complexes and their activity or indeed between the platinum-uptake and the overall activity was not established. However the complexes generally showed improved activity relative to their free ligands and primary testing indicated apoptotic cell death (programmed cell death) is induced in all cell lines on exposure to cytotoxic quantities of the complexes.

Within the scope of this work a range of platinum(II)/(IV) mononuclear and platinum(IV) dinuclear complexes were described. $\alpha,\omega$-Bis(azol-1-yl) compounds with flexible spacers proved versatile ligands affording mononuclear (bidentate and tridentate) and dinuclear complexes, depending on the initial platinum precursor complex. The platinum metallacrown ethers prepared using these $\alpha,\omega$-bis(azol-1-yl) ligands represent a new family of metallacrown ether complexes. The weak interaction between these metallacrown ether hosts and the dialkylammonium ion guests studied herein may provide a basis for the assembly of more complicated interlocking molecules such as rotaxanes and catenanes, although further investigation is required. The moderate anticancer activity of these organometallic
platinum(IV) metallacrown ether complexes is a new departure from the traditional inorganic platinum(II) complexes tested for such properties and contributes to a growing number of bioorganometallic complexes. Taken with the receptor studies, the cancerostatic activity of these metallacrown ethers demonstrates the versatile properties of these complexes.

Crystal structure of [PtBr$_2$Me$_2$(4-CN-py)$_2$], 1f

Compound 1f crystallized in the triclinic space group $P\overline{1}$ and contains two similar symmetry independent molecules per asymmetric unit. The arrangement of the ligating atoms around the respective platinum(IV) atoms is approximately octahedral. The Br1–Pt1–Br2 angle (175.8(1)$^\circ$) deviates significantly from the expected range of values for similar complexes with mutually *trans* bromo ligands bound to a hexacoordinated platinum (median 178.9$^\circ$; lower/upper quartile 177.5/180.0$^\circ$; $n = 48$; $n =$ number of observations).$^{60}$ The Pt1–N3 bond length (2.273(8) Å) is slightly longer than expected for Pt(IV)–N bonds *trans* configured to a ligating carbon atom (median 2.156 Å; lower/upper quartile 2.135/2.194 Å; $n = 402$).$^{60}$ The Pt–Br bond lengths (2.449(1)–2.454(1) Å) and Pt–C bond lengths (2.05(1)–2.07(1) Å) are typical for bonds of these types [a–c,e].$^{50,61}$

The 4-cyanopyridine ligands of both molecules are bend out of the C–Pt–N axes as given by the Pt–N···*para*-C angles. In the most extreme case the Pt1–N1···C5 angle is 165.9(5)$^\circ$ while the Pt1–N3···C11 angle is 173.7(4)$^\circ$ (178.8 (5) and 174.4(5)$^\circ$, respectively, in the second molecule). The Cambridge Structural Database (CSD) reveals a median of 175.8$^\circ$ (lower/upper quartile 173.1/177.9$^\circ$; $n = 104$) occurs for this angle between any transition metal and a non-bridging 4-cyanopyridine ligand.$^{60}$ Only a small number of structures are known with angles of 168$^\circ$ or less and bending in these structures is generally attributed to packing within the crystal or electron repulsions between ligands on the same molecule.$^{62}$
Appendix 2

Crystal structure of cis-[PtBr₂(PPh₃)₂]·CHCl₃, 4f·CHCl₃

cis-[PtBr₂(PPh₃)₂]·CHCl₃ crystallized in the triclinic space group P̅T with no evidence of any unusual intra- or intermolecular contacts. A search of the CSD reveals Pt–P bond lengths with a median of 2.243 Å (lower/upper quartile 2.232/2.255 Å; n = 36) and non-bridging Pt–Br bond lengths with a median of 2.479 Å (lower/upper quartile 2.469/2.490 Å; n = 36) in tetracoordinated platinum(II) complexes.⁶⁰ Thus, the Pt–P and Pt–Br bond lengths of 3f·CHCl₃ are close to these ranges. In addition, bond angles surrounding the central platinum atom deviate from the ideal values somewhat more so than the angles in the trans-[PtBr₂(PPh₃)₂].³⁷b

Experimental

[PtBr₂Me₂(4-CN-py)₂] (1f)

4-Cyanopyridine (11.5 mg, 0.11 mmol), [(PtBr₂Me₂)₂] (21.0 mg, 0.055 mmol) and CHCl₃ (5 ml) were stirred under anaerobic conditions in a Schlenk vessel. After stirring for 8 h the solvent was reduced (ca 1 ml) and a yellow powder was precipitated on addition of pentane (ca 10 ml). Single crystals suitable for X-ray analysis were obtained by slow evaporation of a chloroform solution. Yield: 27 mg (82%). T_{dec}: 148 °C; Anal. Calc. for C₁₄H₁₄Br₂N₄Pt, %: C, 28.35; H, 2.38; N, 9.45. Found, % C, 27.82; H, 2.67; N, 9.45. ¹H NMR (400 MHz, CDCl₃): δ 2.07 (s+d, ²J_{Pt,H} = 72.2 Hz, 6H, C₃H), 7.65 (d, ³J_{H,H} = 6.4 Hz, 4H, C₃H), 9.22 (d+dd, ³J_{H,H} = 6.4 Hz, ³J_{Pt,H} = 11.8 Hz, 4H, C₂H). ¹³C NMR (100 MHz, CDCl₃): δ −8.1 (s+d, ¹J_{Pt,C} = 518.9 Hz, CH₃), 115.1 (s, CN), 123.0 (s, C¹), 127.5 (s+d, ³J_{Pt,C} = 10.5 Hz, C₃H), 152.0 (s+d, ²J_{Pt,C} = 6.0 Hz, C²H). ¹⁹⁵Pt NMR (107 MHz, CDCl₃): δ −2377 (s).
Appendix 2

**Tetradeuterated [PtBr₂Me₂(H-pz)₂]** (2f)

Complex 2f was observed by adding a 1:1 mole ratio of [(PtBr₂Me₂)ₙ] (14 mg, 0.03 mmol) and pyrazole (2 mg, 0.03 mmol) to CD₃OD (0.7 ml) for 88 days or alternatively by addition of a 1:1 mole ratio of [PtBr₂Me₂(H-pz)₂] (5a) (16 mg, 0.03 mmol) and [(PtBr₂Me₂)ₙ] (12 mg, 0.03 mmol) to CD₃OD (0.7 ml) for 16 days. By either approach spectra show a mixture of 2f, [PtBr₂Me₂(CD₃OD)₂] and 5a but eventually only 2f. Signals from 2f, ¹H NMR (400 MHz, CD₃OD): δ 1.84 (s+d, ²Jₚₜ,H = 72.6 Hz, 6H, CH₃), 7.69 (m, 2H, C₅H), 8.00 (m, 2H, C³H). ¹³C NMR (125 MHz, CD₃OD): δ –10.4 (s, CH₃), 107.0 (s, ¹Jₖ,D = 27.4 Hz, C⁴H), 131.5 (s, C⁵H), 140.5 (s, C³H). Signals for [PtBr₂Me₂(CD₃OD)₂], ¹H NMR (400 MHz, CD₃OD): δ 2.02 (s, ²Jₚₜ,H = 80.9 Hz, 6H, CH₃), 6.37 (m, 2H, C₄H), 7.69 (m, 2H, C⁵H), 8.00 (m, 2H, C³H). ¹³C NMR (125 MHz, CD₃OD): δ –10.4 (s, CH₃), 107.0 (s, C⁴H), 131.5 (s, C⁵H), 140.5 (s, C³H). Mass spectrum: calc. m/z for ([C₈H₁₀Br₂D₄N₄Pt]⁺) 525.9; found 525.9; m/z (Intensity calcld/found) for cationic radical [C₈H₁₀Br₂ D₄N₄Pt]⁺, %) 522 (37/59), 523 (40/81), 524 (99/95), 525 (79/100), 526 (100/72), 527 (44/47), 528 (29/44).

**Preparation of [PtCl₂((Ph)₂P(CH₂CH₂O)₂CH₂CH₂P(Ph)₂)]** (3f)³⁵

By analogy to a procedure with [PtCl₂(cod)] and longer α,ω-bis(phosphino) polyether ligands.⁴d In brief, [PtCl₂(nbd)] (55 mg, 0.15 mmol), (Ph)₂P(CH₂CH₂O)₂CH₂CH₂P(Ph)₂ (76 mg, 0.16 mmol) and distilled methylene chloride (10 ml) were added to a Schlenk under anaerobic conditions. After stirring 30 min the volume of the transparent reaction mixture was reduced (2 ml) and the product, a white powder, precipitated upon addition of methanol (6 ml) at 0 °C. Yield 69 mg (61%). As per literature except ³¹P NMR (202 MHz, CDCl₃): δ 11.5 (s+d, ¹Jₚₜ,P = 3712 Hz).

**Preparation of cis-[PtBr₂(PPh₃)₂]** (4f)³⁷a

[(PtBr₂Me₂)ₙ] (15 mg, 0.04 mmol), PPh₃ (20 mg, 0.08 mmol) and C₆D₆ were added to an NMR tube and the tube was secured and sealed. After shaking for 48 h the undissolved pale yellow powder was filtered off and washed with benzene (5 ml) and methanol (5 ml). Single crystals suitable for X-ray diffraction were obtained by slow
evaporation of a chloroform solution. $^{31}$P NMR (202 MHz, CDCl$_3$) $\delta$ 14.7 (s+d, $^1J_{\text{Pt,P}}$ = 3605 Hz).

**Preparation of $[\{\text{PtBr}_2\text{Me}_2(4,4''\text{-bipy})\}]\langle 5f \rangle$**

$[\{\text{PtBr}_2\text{Me}_2\}]_n$ (54 mg, 0.14 mmol), 4,4''-bipyridine (23 mg, 0.14 mmol) and chloroform (ca. 10 ml) were added to a flask. The reaction mixture was gently refluxed for approximately 16 h before the mixture was cooled and filtered in air. The powder was washed with MeOH (10 ml) and CHCl$_3$ (10 ml). The finely divided yellow product was dried in air. Yield 76 mg (75%) $T_{\text{dec}}$: 158 °C. Anal. Calc. for C$_{12}$H$_{14}$Br$_2$N$_2$Pt, %: C, 26.63; H, 2.61; N, 5.18. Found, % C, 26.60, H, 2.83, N, 4.84. $^1$H NMR (400 MHz, (CD$_3$)$_2$NCOD): $\delta$ 2.06 (s+d, $^2J_{\text{Pt,H}}$ = 70.8 Hz, 6H, CH$_3$), 8.17 (m, 4H, C$_3^H$), 9.06 (d, $^3J_{\text{H,H}}$ = 6.6 Hz, 4H, C$_2^H$). $^{13}$C NMR (125 MHz, (CD$_3$)$_2$NCOD): $\delta$ –8.1 (s+d, $^1J_{\text{Pt,C}}$ = 516.6 Hz, CH$_3$), 124.7 (s(br), C$_3^H$), 146.9 (s, C$^1$), 152.6 (s(br), CH$_3$). $^{195}$Pt NMR (107 MHz, C$_4$D$_8$O): $\delta$ –2343 (s). IR: $\nu$ (cm$^{-1}$) 3442(s), 3072(w), 2981(w), 2910(m), 2813(w), 1608(s), 1533(w), 1489(w), 1414(s), 1216(s), 1070(m), 1013(w), 812(s), 638(s), 505(w).
Crystal data and structure refinement for 1f (STADI997).

Empirical formula \( \text{C}_{14}\text{H}_{14}\text{Br}_{2}\text{N}_{4}\text{Pt} \)

Formula weight 593.20

Temperature 220(2) K

Wavelength 71.073 pm

Crystal system Triclinic

Space group \( \text{P} \bar{T} \)

Unit cell dimensions
\[
a = 964.4(2) \text{ pm} \quad \alpha = 94.75 (2)^\circ \\
b = 1217.4(2) \text{ pm} \quad \beta = 105.04 (2)^\circ \\
c = 1547.2(3) \text{ pm} \quad \gamma = 95.05 (2)^\circ 
\]

Volume 1.737 (6) \( \text{nm}^3 \)

\( Z \) 4

Density (calculated) 2.268 \( \text{mg/m}^3 \)

Absorption coefficient 12.68 \( \text{mm}^{-1} \)

\( F(000) \) 1096

Theta range for data collection 1.7 to 25.1°.

Index ranges \(-11 \leq h \leq 11, -14 \leq k \leq 14, -18 \leq l \leq 18\)

Reflections collected 9997

Independent reflections 6530 \([R_{int} = 0.0584]\)

Completeness to theta = 24.49° 98.1 %

Absorption correction psi-scans

Refinement method Full-matrix least-squares on \( F^2 \)

Data/restraints/parameters 6057/0/383

Goodness-of-fit on \( F^2 \) 1.107

Final \( R \) indices \([I>2\sigma(I)]\) \( R_1 = 0.0518, wR^2 = 0.1322 \)

\( R \) indices (all data) \( R_1 = 0.0673, wR^2 = 0.1468 \)

Largest diff. peak and hole 2.032 and −2.066 e.Å\(^{-3}\)
Crystal data and structure refinement for **4f·CHCl₃** (ipds2796).

Curriculum Vitae

Personal details:
Name: Mairéad Eilís Kelly
Date of Birth: October 22\textsuperscript{th} 1980
Place of Birth: Limerick, Ireland
Nationality: Irish

Education details:
Third level:
\begin{itemize}
  \item Studying for: PhD (Dr. rer. nat.), Inorganic Chemistry.
    Martin-Luther Universität Halle-Wittenberg, Kurt-Mothes Str. 2, Halle (Saale), 06120, Germany. (Commenced: 10/2004, defended 12/2007)
  \item MPhil, Analytical Chemistry.
    The University of Hull, Cottingham Road, Hull, HU6 7RX, England. (09/2002 to 09/2004)
  \item BSc, Chemistry (2.1).
    University College Cork, College Road, Cork, Ireland.
    (09/1998 to 06/2002)
\end{itemize}

Second Level:
\begin{itemize}
  \item Leaving Certificate, 495/600 points.
  \item St. Joseph’s Secondary School, Spanish Point, Ireland.
  \item Subjects: Chemistry, Physics, Biology, Mathematics, German, English, Irish.
\end{itemize}
(09/1993 to 06/1998)
Eidesstattliche Erklärung

Hiermit erkläre in an Eides statt, dass ich die vorliegende Arbeit selbständig verfasst und keine anderen Hilfsmittel als die angegebenen verwendet habe. Ich habe die Arbeit an keiner anderen Hochschule vorgelegt und mich zu keinem früheren Zeitpunkt um den Doktorgrad beworben.

Mairéad Eilís Kelly
Acknowledgements

The author of this thesis wishes to gratefully acknowledge those who contributed to the work presented within this thesis.

The Deutsche Forschungsgemeinschaft, the DAAD and Martin-Luther-Universität are gratefully acknowledged for their financial support.

Sincere thanks to Dr. S. Gómez-Ruiz, Prof. K. Merzweiler and Dr. Ch. Wagner for X-ray crystallographic measurements and for discussion relating to these measurements. Many thanks also to Dr. R. Kluge, Dr. J. Schmidt and Frau E. Leißering for performing mass spectrometric analyses and for discussion relating to these analyses. Thanks to Dr. Ströhl and his team for NMR investigations and Dr. T. Müller for thermogravimetric measurements.

A. Dietrich, Dr. B. Kalinowski, Dr. G. N. Kaludеровић and Dr. R. Paschke are thanked for their contributions to the anticancer investigations presented herein. Their efforts, expertises and discussions were much appreciated and are gratefully acknowledged.

A very sincere thanks to all the members of the inorganic institute past and present with whom I had the pleasure of working with on a daily basis and from whom I learned a great deal, particularly Conni, Goran, Marcin, Michael (B. and W.), Sebastian, Ronald and Renate.

Thanks are extended to Prof. D. Steinborn for the opportunity to join his research group and for all his support and discussion throughout the duration of my doctoral studies.

Finally, many thanks to Dr. Harry Schmidt for his excellent supervision of the thesis work and for all the support and assistance given throughout the duration of my doctoral studies.
