cyclo-Tetrakis(μ -2,4,6-trimethylphenyl- κC^1 : κC^1)-bis(trimethylphosphane)-1 κP ,3 κP -tetracopper(I)

Phil Liebing and Kurt Merzweiler*

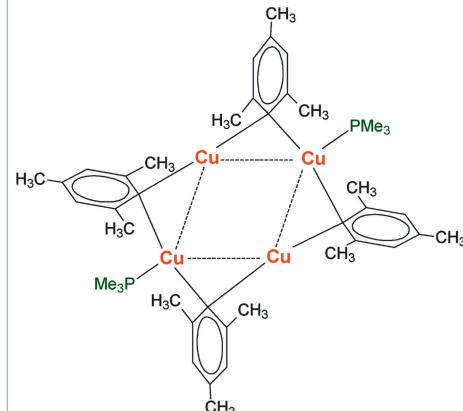

Martin-Luther-Universität Halle, Naturwissenschaftliche Fakultät II, Institut für Chemie, Germany. *Correspondence e-mail: kurt.merzweiler@chemie.uni-halle.de

The title compound, $[Cu_4(C_9H_{11})_4(C_3H_9P)_2]$ or $[Cu_4(Mes)_4(PMe_3)_2]$ ($Mes = 2,4,6$ -trimethylphenyl), was synthesized from copper(I) mesityl and trimethylphosphane in THF as solvent. The molecular structure of the complex has C_2 symmetry and consists of four copper(I) atoms bridged by four μ -mesityl groups, giving an eight-membered puckered $\{Cu_4C_4\}$ ring. Additionally, two copper(I) atoms at opposite corners of the Cu_4 rhomb are each linked to a terminal PMe_3 ligand. The PMe_3 -bearing copper(I) atoms exhibit a distorted trigonal-planar coordination mode whereas the remaining Cu atoms linked to two mesityl groups are nearly linearly coordinated.

Chemical scheme

Structure description

Among Cu^1 organyls, mesitylcopper is one of the most extensively studied compounds. Since its first synthesis in 1981 (Tsuda *et al.*, 1981), mesitylcopper has found widespread application in preparative organometallic chemistry (Stollenz & Meyer, 2012). In the solid state, mesitylcopper can exist as a pentamer ($CuMes_5$) (Gambarotta *et al.*, 1983; Meyer *et al.*, 1989) or as a tetramer ($CuMes_4$) (Eriksson & Håkansson, 1997). On treatment with donor ligands L , mesitylcopper displays different reaction patterns depending on the nature of L . In the case of tetrahydrothiophene (THT), the reaction proceeds under retention of the tetranuclear cluster structure to form $[Cu_4(Mes)_4(THT)_2]$ (Gambarotta *et al.*, 1983; Meyer *et al.*, 1989). Treatment of mesitylcopper with PPh_3 in toluene led to a compound $[CuMes(PPh_3)_2] \cdot C_7H_8$ with a yet unknown crystal structure (Meyer *et al.*, 1989). The reaction with dppe (1,2-bis(diphenylphosphino)ethane) causes a degradation of the Cu_4Mes_4 cluster to give a cuprocuprate $[(dppe)_2Cu][CuMes_2]$ (Leoni *et al.*, 1983).

In order to get some insight into the reactivity of mesitylcopper towards sterically less demanding phosphanes, trimethylphosphane was chosen as a ligand. Treatment of a

Symmetry code: (i) $-x + 1, y, -z + \frac{1}{2}$.

solution of mesitylcopper in THF with PMe_3 at room temperature led to the formation of the tetranuclear complex $[\text{Cu}_4(\text{Mes})_4(\text{PMe}_3)_2]$ (**1**).

The molecular structure of (**1**) comprises four copper(I) atoms that are linked by four μ -mesityl groups to give an eight-membered $\{\text{Cu}_4\text{C}_4\}$ ring (Fig. 1). Additionally, two copper atoms at diametrically opposite positions of the ring are each linked to a terminal PMe_3 group. The tetranuclear copper complex exhibits crystallographic C_2 symmetry with the diad axis passing through the center of the C10—C15 bond. The rhombic arrangement of the copper atoms is nearly planar, with marginal deviations of 0.0087 \AA from the mean plane through the four copper atoms. The relatively small Cu···Cu distances at the edges of the rhomb [2.4603 (5)—2.4625 (5) \AA] suggest cuprophilic interactions. The Cu···Cu separations between the copper atoms at opposite corners of the rhomb are 4.2013 (5) \AA for $\text{Cu}_2\cdots\text{Cu}_2^i$ [symmetry code: (i) $-x + 1, y, -z + \frac{1}{2}$] and 2.5657 (7) \AA for $\text{Cu}_1\cdots\text{Cu}_1^i$. Similar shaped arrangements of four Cu atoms were observed in the derivatives $[\text{Cu}_4(\text{Mes})_4(\text{THT})_2]$, $[\text{Cu}_4(o\text{-Tol})_4(\text{SMe}_2)_2]$ (Lend-

ers *et al.*, 1991) and $[\text{Cu}_4\text{Ph}_4(\text{SMe}_2)_2]$ (Olmstead & Power, 1990). Complex (**1**) exhibits two types of differently coordinated Cu atoms (Table 1). Cu1 is surrounded by two mesityl groups with Cu—C distances of 2.005 (3) and 2.006 (3) \AA . In comparison with $[\text{Cu}_4\text{Mes}_4]$, the Cu—C distances are slightly enlarged by around 0.014 \AA . However, the bending of the C1—Cu1—C10ⁱ unit [$138.3 (1)^\circ$] is clearly more pronounced than in $[\text{Cu}_4\text{Mes}_4]$ ($164.05\text{--}165.70^\circ$). Apart from two mesityl groups, Cu2 bears a PMe_3 unit as a third ligand. The increased coordination number leads to a further enlargement of the Cu—C distances with values of 2.093 (3) and 2.095 (3) \AA . The coordination around Cu2 is planar with a C—Cu—C angle of $163.0 (1)^\circ$ and C—Cu—P angles of $97.9 (1)^\circ$ and $99.0 (1)^\circ$ (sum of the angles around Cu2: 359.9°). Comparison of the bond lengths of compound (**1**) and related $[\text{Cu}_4\text{Mes}_4L_2]$ complexes reveals that the ligand PMe_3 leads to a larger increase of the Cu—C distances for the tricoordinate copper atoms than other ligands investigated so far. In $[\text{Cu}_4\text{Mes}_4L_2]$ complexes with $L =$ piperidine, allyl methyl sulfide, 2,5-di-thiahexane, tetrahydrothiophene and bis[2-[1-(dimethylamino)ethyl]phenylthiolato]magnesium, the mean Cu—C distances for the tricoordinated copper atoms are in the range 2.054–2.064 \AA . In the case of the dicoordinated Cu there is no particular effect. Furthermore, there is a slight influence on the C—Cu—C angles for the dicoordinated [$138.3 (1)^\circ$] and the tricoordinate copper atoms [$163.0 (1)^\circ$], which are smaller than in the $[\text{Cu}_4\text{Mes}_4L_2]$ complexes mentioned above ($140.3\text{--}142.8^\circ$ and $165.0\text{--}170.2^\circ$, respectively).

The molecular packing reveals no special supramolecular features (Fig. 2). Most of the contacts are of the van der Waals type with some minor participation of C—H··· π interactions: C17—H17A···Cg2ⁱ with $d(\text{H}\cdots\text{Cg2}) = 2.87 \text{\AA}$, C17—H17A···Cg2 = 167° [Cg2 is the centroid of the C10—C15 ring; symmetry code: (i) $-x, y, \frac{1}{2} - z$].

Generally, X-ray crystallographic studies on Cu^I aryl compounds with auxiliary phosphane ligands are relatively rare. According to the CSD database (Groom *et al.*, 2016), there are two compounds of the type $[\text{RCu}(\text{PR}'_3)]$ [$R = (2,2'',4,4'',6,6''\text{-hexamethyl-1,1':3',1''-terphenyl-2'-yl})$, $R' = \text{Ph}$

(Niemeyer, 2003), *R'* = Et (Runghanaphatsophon *et al.*, 2016], containing nearly linear C—Cu—P units. Typically, this structural motif occurs if further molecular aggregation is prevented by sterically demanding aryl groups. The Cu—C bond lengths in [RCu(PR'₃)₂]-type compounds are 1.922 Å for the PPh₃ derivative (Niemeyer, 2003) and 1.930 Å in the case of the PEt₃ co-ligand. The shortening of the Cu—C distances in comparison with [Cu₄(Mes)₄(PMe₃)₂] may be attributed to the lower coordination number of the copper atoms. The same effect is also visible for the Cu—P distances of 2.189 Å (Niemeyer, 2003) and 2.200 Å (Runghanaphatsophon *et al.*, 2016), respectively. Furthermore, there is a terphenyl copper complex of the type [RCu(PR'₃)₂] (*R'* = Et) with two phosphane units attached to copper. In this case, the copper atom exhibits a distorted trigonal-planar coordination with markedly enlarged Cu—C (1.979 Å) and Cu—P (2.250 and 2.256 Å) distances (Runghanaphatsophon *et al.*, 2016).

The CSD database contains five entries for [Cu₄Mes₄*L*₂] complexes, with *L* = THT (Gambarotta *et al.*, 1983; Meyer, *et al.*, 1989), piperidine (Sung *et al.*, 2015), allyl methyl sulfide or 2,5-dithiahexane (Kokoli *et al.*, 2013). There are also some heterometallic Cu₄Mes₄ complexes with bis(thiophenoato)magnesium units as ligands (Knottner *et al.*, 1990).

Synthesis and crystallization

A solution of 0.46 g (2.5 mmol) mesitylcopper (Meyer *et al.*, 1989) in 10 ml of THF was treated with 0.13 ml (1.25 mmol) of

trimethyl phosphane. The reaction mixture was stirred for one h at 293 K. The reaction product [Cu₄(Mes)₄(PMe₃)₂] (**1**) was precipitated by the addition of 30 ml of *n*-hexane. After filtration, the colorless product was washed with diethyl ether (2 × 5 ml) and dried under vacuum. Single crystals suitable for X-ray analysis were obtained by slow diffusion of *n*-hexane into a THF solution of the product. Yield: 0.33 g (60%). C₄₂H₆₂Cu₄P₂ (883.01 g mol⁻¹). Analysis: Cu 29.0% (calc. 28.8%). IR (cm⁻¹) 2997(w), 2963(m), 2901(m), 2855(w), 2842(w), 2802(w), 2705(w), 1589(w), 1637(w), 1376(w), 1448(w), 1418(m), 1362(w), 1302(w), 1286(m), 1257(w), 1215(w), 1164(w), 1024(w), 939(s), 873(w), 844(s), 730(s), 710(w), 670(m), 576(w), 538(m), 484(w), 357(m), 328(m), 301(m), 275(w). ¹H NMR (C₆D₆): δ 0.60 (s br, 18H; PCH₃), 2.08 (s, 12H; *p*-CH₃), 2.73 (s, 24H; *o*-CH₃), 6.68 (s, 8H; CH). ¹³C{¹H} NMR (C₆D₆): δ 15.4 (s br; PCH₃), 21.4 (s; *p*-CH₃), 28.7 (s; *o*-CH₃), 125.6 (s; CH), 127.4 (s; CCu₂), 134.4 (s; *p*-CCH₃), 150.0 (s; *o*-CCH₃). ³¹P{¹H} NMR (C₆D₆): δ -44.6 (s br).

Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2.

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
