

**The genetic Characterization of RNA-directed
Transcriptional Gene Silencing in *Arabidopsis thaliana***

Dissertation

zur Erlangung des akademischen Grades

doctor rerum naturalium (Dr. rer. nat.)

vorgelegt der

Naturwissenschaftlichen Fakultät I

- Biowissenschaften -

der Martin-Luther-Universität Halle-Wittenberg

von Andreas Finke

geboren am 11.09.1981 in Wolfen

Gutachter:	Prof. Dr. Gunter Reuter Dr. Michael Florian Mette PD Dr. Ortrun Mittelsten Scheid
------------	---

Promotionsgesuch eingereicht am:	02. April 2013
Tag der öffentlichen Verteidigung:	24. September 2013

„In der Wissenschaft gleichen wir alle nur den Kindern, die am Rande des Wissens hier und da einen Kiesel aufheben, während sich der weite Ozean des Unbekannten vor unseren Augen erstreckt.“

Sir Isaac Newton (1643 – 1727)

Acknowledgment

I would like to thank Dr. Michael Florian Mette for giving me the opportunity to be part of the epigenetics group, continuous support, guidance, helpful suggestions invaluable effort and patience in correcting this thesis.

I thank the members of the research group of Epigenetics Markus Kuhlmann, Che How Teo and Branimira Borisova Todorova for helpful discussions, suggestions, scientific advices and for keeping a nice working atmosphere in the lab.

Furthermore I want to express my gratitude to Christa, Beate and Inge for their excellent technical support.

I am very thankful to Dr. Renate Schmidt, for helpful discussions and suggestions.

I want to express my gratitude to Ines Walde and Susanne König for their excellent work in the IPK sequencing facility and for many cheerful discussions.

Moreover I want to thank Martin Mascher for analyzing the next generation sequencing data.

I also thank Prof. Gunter Reuter, Dr. habil. Ortrun Mittelsten Scheid and Dr. Michael Florian Mette, for their acceptance to be part of the evaluation committee for my PhD work.

I thanks to all colleagues outside of the Epigenetics group that helped to keep my time in the IPK in good remembrance.

Mein allergrößtes Dankeschön gilt meiner Familie, meine Eltern Albrecht und Christine, meine Schwester Marianne und meine Freundin Alexandra die mich während der Zeit meiner Doktorarbeit unterstützt und immer wieder motiviert haben.

Ein besonderes Dankeschön geht darüber hinaus an Alice Mosch für die hilfreichen Gespräche zu (fast) jeder Tages und Nachtzeit.

1 INTRODUCTION

1.1 EPIGENETICS

Organisms are subjected to various developmental processes throughout their life cycle. The proper confinement of these processes requires a reliable temporal and spatial regulation of gene expression. Nevertheless, the relevant executable information, the genes encoded by the storage medium DNA, usually stays essentially the same in every cell of an individual. This also seems reasonable, as developmental regulation based on DNA sequence change would face the problem that coordinated emergence of identical alterations (mutations) in the primary information in multiple cells would be statistically unlikely. Hence, the differential execution of genetic information in differentiated cells needs to be regulated in other ways. One option is *via* the regulation of the accessibility of particular parts of information, that is, particular regions of the DNA.

Extensive compaction of the DNA double strand into higher order structures is necessary to facilitate the incorporation of genomic DNA into the eukaryote nucleus. The first level of compaction happens at nucleosomes, the basic repeating unit of eukaryotic chromatin (Kornberg and Klug, 1981) consisting of an octamer core particle, linker histone H1 and DNA. The core particle is formed from two copies each of the four major histone proteins H2A, H2B, H3 and H4, around which 147 bp of superhelical DNA double strand are wrapped. Individual core particles are separated by 20 to 80 bp of DNA, to which H1 is bound during interphase. The wrapping of the DNA around the core particles leads to the formation of a beads-on-a-string structure, which can be observed electron-microscopically under non-physiological conditions. In living cells, this string structure is supposed to form a 30 nm fiber structure, which can undergoes further steps of compaction to finally form the highly condensed chromosomes present in metaphase (Van Holde, 1988; Bednar *et al.*, 1998).

The whole entity of DNA and its associated proteins in the eukaryote nucleus is termed chromatin. In addition to the compaction of the nuclear DNA, a further important function of chromatin is the selective regulation gene expression in the context of cell differentiation. Chromatin-mediated transcriptional regulation can be mitotically and in some cases meiotically stable, that is, heritable, without the involvement of any changes

of DNA sequence. The deciphering of the mechanisms regulating the access to genetic information is the main scope of epigenetic research.

Pioneering cytogenetic experiments using light microscopy led to the definition of two major chromatin states, the relatively more condensed heterochromatin and the more open euchromatin. Heterochromatin can be further divided into constitutive heterochromatin, which is late replicating and remains condensed during the cell cycle in virtually all cells of an organism, and facultative heterochromatin, which is formed from euchromatin in a cell type- or condition-specific manner. In the model plant *Arabidopsis thaliana* (*A. thaliana*), the cytogenetically defined constitutive heterochromatin is located in and around the centromeres. It is enriched in repetitive sequences and silenced transposable elements (TEs), but contains only few expressed genes, and therefore is considered to be a low expressing chromatin compartment. In contrast, euchromatin located on the chromosome arms is rich in highly expressed genes and depleted in TEs, and thus is referred to as an actively expressing chromatin compartment.

1.2 MECHANISM OF EPIGENETIC REGULATION

Histone Modifications

The histones H2A, H2B, H3 and H4 forming the nucleosome core are highly basic proteins. While their C-terminal domains arrange into a defined globular structure that binds to the minor groove of DNA, their N-terminal domains are rather unstructured and protrude from the core particle. It is well established that these N-terminal “tails” are subjected to diverse post-translational modifications. Of the many covalent histone modifications known, methylation, acetylation, phosphorylation, sumoylation and ribosylation were so far identified in plants (Berr *et al.*, 2011; Dong *et al.*, 2012; Houben *et al.*, 2007; Luo *et al.*, 2008; Dhawan *et al.*, 2009; Miller *et al.*, 2010; Bannister and Kouzarides 2011). For most of these, the way how the modification alters chromatin structure is not well understood. It is assumed that they affect nucleosome-nucleosome interactions, nucleosome-DNA interactions and / or the interaction of nucleosomes with non-histone proteins and by this regulate transcription and other processes at chromatin level.

Variation in chromatin structure can also be brought about by the incorporation of histone variants. In many eukaryotes, histone proteins are encoded by gene families with functional differentiation of family members. For example, in *A. thaliana* histone variant H3.1 is enriched in silent and variant H3.3 is associated with actively transcribed

chromatin (Stroud *et al.*, 2012). Similarly, the H2A variant H2A.Z marks regions around gene promoters (Zilberman *et al.*, 2008; March-Diáz and Reyes, 2009), and cenH3, which is a more divergent form of histone H3, is located exclusively in centromeric regions, where it plays essential functions including proper segregation of chromosomes (Lermantova *et al.*, 2006).

Methylation of lysine (K) and arginine (R) residues can happen to different levels, as mono-, di- and trimethylation at K and mono- and dimethylation at R, which further increases the diversity of possible histone modification patterns (Naumann *et al.*, 2005; Cloos *et al.*, 2008). The high number of possible combinations of these modifications and their assumed interdependence led to the formulation of the histone code hypothesis, which postulates that the combination of different histone modification at a chromatin region leads to a certain consistent regulatory outcome (Turner 2000; Strahl and Allis, 2001; Jenuwein and Allis, 2001).

Among the known histone modifications, methylation and acetylation of lysine residues located in the N-terminal domains of histone H3 and H4 have been most extensively studied and are thought to be associated with transcriptional activation or repression.

Recently, integrative analyses of histone modification profiles performed in *A. thaliana* revealed the organization of the “epigenome” into four major chromatin states. Actively expressed genes show enrichment for di- and trimethylation of K4 and K36 of H3, while repressed genes within euchromatin are marked by trimethylation of K27 of H3. Furthermore, silenced TEs are marked by monomethylation of K20 of H4 and dimethylation of K9 of H3, while intergenic regions and low expressed genes do not display any prevalent marks (Roudier *et al.*, 2011).

DNA methylation

In eukaryotes DNA methylation refers commonly to the enzymatic transfer of a methyl group (-CH₃) to the cyclic carbon 5 in the pyrimidine ring of cytosine. In contrast to mammals, where methylation in somatic cells is predominantly limited to the cytosines in CG context, DNA methylation in plants is found in CG, CHG and CHH (with H standing for C, A, T) contexts (Ramsahoye *et al.*, 2000; Lister *et al.*, 2009; Cokus *et al.*, 2008). In *A. thaliana*, approximately 7% of the cytosines in cellular DNA are found to be methylated; with 24%, 6.7% and 1.7% of cytosines in CG, CHG and CHH context methylated, respectively (Rohzon *et al.*, 2009; Cokus *et al.*, 2008). Generally, DNA methylation in plants is a mark of heterochromatin and transcriptional inactivation that is

typically associated with a silenced chromatin state and is largely confined to silent repetitive sequences and TEs.

Repression of transposable elements

As mentioned above, in *A. thaliana* the majority of DNA methylation is located in pericentromeric regions of chromosomes, which mainly consist of TEs and other repetitive sequences. Excessive expression of TEs would present a threat to host genome integrity, as frequent random integration would lead to a high incidence of gene disruption. Therefore, repression of TE transcription is necessary. Analysis of TE inactivation in maize first pointed to the importance of DNA methylation in TE silencing (Chandler and Walbot, 1986; Banks *et al.*, 1988). Later on, the loss of DNA methylation in *A. thaliana* was found to cause decondensation of pericentromeric regions, which is accompanied by transcriptional reactivation of previously silenced TEs (Miura *et al.*, 2001; Lippman *et al.*, 2003; Zhang *et al.*, 2006; Mathieu *et al.*, 2007; Blevins *et al.*, 2009). Further, in a more physiological context, the removal of DNA methylation by DNA glycosylase DEMETER (DME) in the vegetative nucleus of pollen in *A. thaliana* causes the transcriptional activation of diverse types of TEs (Slotkin *et al.*, 2009; Hsieh *et al.*, 2009; Gehring *et al.*, 2009).

Parental Imprinting

DME is also involved in parental imprinting in *A. thaliana*, a mechanism leading to the parent-of-origin specific expression of genes during embryogenesis and seed development. Among the few imprinted genes known in *A. thaliana*, the regulation of *MEDEA* (*MEA*), *FLOWERING WAGENINGEN* (*FWA*), *PHERES1* and *FERTILIZATION INDEPENDENT SEED 2* (*FIS2*) are best described (Grossniklaus *et al.*, 1998; Luo *et al.*, 1999; Kinoshita *et al.*, 1999; Kinoshita *et al.*, 2004; Ville-Calzada *et al.*, 1999; Köhler *et al.*, 2005). *MEA*, *FWA* and *FIS2* are only active in the central cell of the female gametophyte (Choi *et al.*, 2002; Kinoshita *et al.*, 2004). After double fertilization, only the maternal alleles are expressed in the endosperm. While inactivity of paternal *FWA* and *FIS2* in endosperm and of both alleles of the two genes in all other tissues seems to depend solely on DNA hypermethylation of direct sequence repeats in upstream of their respective promoters (Kinoshita *et al.*, 2004; Jullien *et al.*, 2006a), silencing of the paternal and maternal alleles of *MEA* and *PHE1*, respectively, seems to involve additional mechanisms despite a clear correlation between DNA methylation in the promoter and transcriptional silencing in *MEA* (Xiao *et al.*, 2003). At these gene loci, histone-modifying Polycomb complexes are required for stable silencing. Silencing at

MEA (Jullien *et al.*, 2006b) as well as at the repressed maternal *PHE1* (Köhler *et al.*, 2005) rather depends on repressive histone marks. Recently, a region in the *MEA* locus was identified that is essential for transcriptional silencing, but is not differentially methylated in endosperm and vegetative tissue, which further supports the assumption of a DNA methylation independent imprinting mechanism (Wöhrmann *et al.*, 2012).

Paramutation

Paramutation is an epigenetic mechanism that refers to an *in trans* inactivation between homologous alleles leading to reproducible and heritable changes in gene expression at one of the alleles (Stam and Mittelsten Scheid, 2005). Paramutation has been mainly studied in maize, but paramutation and paramutation-like phenomena were also observed in other plant species as well as in mice and human (Krebbers *et al.*, 1987; Hagemann *et al.*, 1993; Bennett *et al.*, 1997;). Although the precise underlying mechanism is still enigmatic, a number of structural, genetic and epigenetic requirements for establishment of the silenced state could be identified. A feature found in many paramutation systems are direct or inverted repeat sequences which are, at least in cases like the locus *booster1*, indispensable for the paramutation process (Kermicle *et al.*, 1995; English and Jones, 1998; Walker and Panavas, 2001; Stam *et al.*, 2002; Sidorenko and Chandler, 2008). Furthermore, based on the observation that unsilenced paramutable alleles display low levels of DNA methylation and become methylated and silenced when combined with a paramutagenic allele, an involvement of DNA methylation in paramutation was assumed (Walker and Panavas, 2001; Haring *et al.*, 2010;). This was further supported by forward genetic screens in maize that identified homologs of *A. thaliana* NRPD1, NRPD2a, RDR2 and a SWI2/SNF2-like factor to be essential for paramutation, suggesting the involvement of a RNA-directed DNA methylation-like mechanism (see below) (Dorweiler *et al.*, 2000; Alleman *et al.*, 2006; Hale *et al.*, 2007; Erhard *et al.*, 2009; Sidorenko *et al.*, 2009; Stonaker *et al.*, 2009; Law *et al.*, 2011).

1.3 ESTABLISHMENT AND MAINTENANCE OF DNA METHYLATION

DNA methyltransferases

Cytosine methylation is conferred to DNA post-replicative by a set of DNA methyltransferases (DMTase). All eukaryotic DMTases identified so far share a number of common amino acid motives in their respective methyltransferase domains (MTase), which are involved in recognition of the target site, binding of the co-factor S-adenosyl

Introduction

methionine and in catalyzing the transfer of the methyl group (Posfai *et al.*, 1989; Kumar *et al.*, 1994; Goll and Bestor, 2005). As these sequence motifs are also conserved in the DNA methyltransferases of bacteria, eukaryotic and bacterial DMTases share a common evolutionary root.

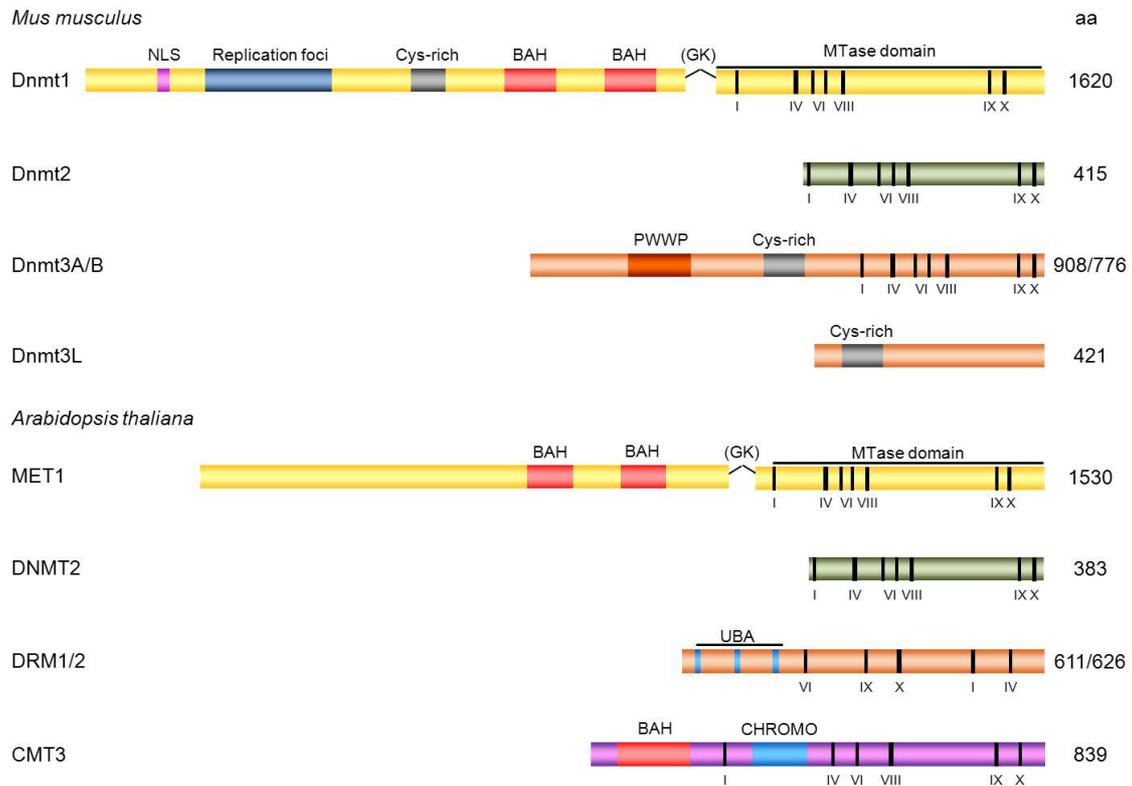

Figure 1: Classes and Domain organisation of DNA methyltransferases of *M. musculus* and *A. thaliana*.

Positions and order of conserved sequence motifs in the MTase domain are indicated. Figure 1 was adapted from Goll and Bestor 2005.

Phylogenetic studies comparing the MTase domains of eukaryotic DNMTases led to the definition of four families (Figure 1). While homologs of three families, Dnmt1, Dnmt2 and Dnmt3, have been identified in plant and non-plant species, the chromodomain-containing CHROMOMETHYLASE family is plant specific (Henikoff and Comai, 1998).

In *A. thaliana*, 10 genes for proteins displaying sequence homology to MTase domains were identified (Finnegan and Kovac, 2000). Four putative MTases, termed *METHYLTRANSFERASE 1 (MET1)* and *METHYLTRANSFERASE1-LIKE (MEL)*, belong to the *Dnmt1* family. *DOMAINS REARRANGED METYHLTRANSFERASE (DRM) 1 to 3* are homologs of *Dnmt3* and *CHROMOMETHYLASE (CMT) 1 to 3* are the members of the plant specific DMTase family. In addition, one *Dnmt2*-homolog is encoded in the *A. thaliana* genome, which is only very lowly expressed and to which no function in genomic DNA methylation is designated to.

In *A. thaliana*, like in mammals, a stark correlation of methylation in one strand with methylation on the opposite strand exists for strand-symmetric CG sites (Bird, 2002; Cokus *et al.*, 2008). The re-establishment of full CG context methylation on hemimethylated DNA double strand after DNA replication depends on the activity of DMTase MET1, SWItch2/Sucrose non fermenting 2 (SWI2/SNF2) chromatin remodeling factor DECREASE IN DNA METHYLATION (DDM1) and VARIANT IN METHYLATION (VIM) proteins 1 to 3 (Vongs *et al.*, 1993; Woo *et al.*, 2007; Woo *et al.*, 2008). Furthermore, the interaction of MET1 with HISTONE DEACETYLASE 6 (HDA6) is necessary to maintain CG context methylation at certain loci such as the centromeric 180 bp repeats (Aufsatz *et al.*, 2002b; To *et al.*, 2011; Liu *et al.*, 2012). The molecular mechanisms underlying the CG context methylation maintenance machinery is poorly understood in plants; however, the existence of proteins analogous to MET1, VIMs and DDM1 in mammals might suggest that similar mechanisms are acting in mammals and in plants (Law and Jacobsen, 2010).

Like in the case of the CG context, the positioning of the cytosines in CHG context is symmetric on the two strands of double stranded DNA. Consistently, a stark correlation of methylation in one strand with the methylation in the opposite strand was reported for the CHG context, which would suggest the action of a maintenance mechanism similar to the one for CG methylation maintenance (Cokus *et al.*, 2008). However, the maintenance of methylation in CHG context differs significantly from CG methylation maintenance. The majority of CHG methylation in *A. thaliana* depends on the DMTase CHROMOMETHYLASE3 (CMT3) and on H3K9-specific SUPPRESSOR OF VARIATION3-9 HOMOLOG (SUVH) histone methyltransferases SUVH4, SUVH5, SUVH6 (Jackson *et al.*, 2002; Malagnac *et al.*, 2002; Ebbs *et al.*, 2006; Pontvianne *et al.*, 2012). Based on early *in vitro* experiments, which showed affinity of the chromodomain of CMT3 to peptides dimethylated at K9 of histone H3 and the decrease of CHG methylation in H3K9me₂-deficient mutants, it was concluded that these histone marks serve to label CMT3 methylation target sites (Lindroth *et al.*, 2004). Recently, this interpretation was confirmed by a genome-wide superimposition of CMT3 binding sites and H3K9me₂-marked nucleosomes (Du *et al.*, 2012). Moreover, the involvement of HDA6 in CHG methylation maintenance at several loci is also well documented (Aufsatz *et al.*, 2002; Liu *et al.*, 2012; To *et al.*, 2011).

In contrast to CG and CHG context, the cytosines in CHH context do not have a symmetrically positioned counterpart on the complementing DNA strand. Thus, the

mechanism for the propagation of methylation in CHH context needs to be more complex and involves persistent *de novo* methylation by DRM-type DNA methyltransferases. In contrast to mammalian *de novo* methyltransferases Dnmt3a and Dnmt3b, the MTase domain of DRM-type enzymes displays a rearranged order of catalytic motives (Figure 1; Cao *et al.*, 2001). Furthermore, DRM proteins contain three UBA domains (UBIQUITIN ASSOCIATED) able to bind ubiquitin, which are supposed to direct DRMs to the sites of *de novo* methylation (Mueller and Feigon, 2002; Kozlov *et al.*, 2007; Henderson *et al.*, 2010). Although DRMs are encoded by three genes in *A. thaliana*, only *DRM1* and *DRM2* encode proteins that contain all invariant residues necessary for catalytic activity (Cao *et al.*, 2001; Cao and Jacobsen 2002; Julien *et al.*, 2012). In contrast, *DRM3* is not expected to display catalytic activity due to the absence of the invariant cytidylprolyl dipeptide of motif IV, which is thought to be necessary for recognition and stabilization of the cytosine in the active center and an additional mutation of conserved residues in motive IX and X (Henderson *et al.*, 2010, Bestor and Verdine, 1994).

Sequence specificity is conferred to DRM by an RNA interference (RNAi)-related mechanism known as RNA-directed DNA methylation (RdDM) first observed in *Nicotiana tabacum* infected with potato spindle tuber viroid (Wassenegger *et al.*, 1994). The critical requirement for RdDM is formation of double-stranded (ds)RNA, was demonstrated by Pol II-mediated transcription of inverted repeat (IR) structures. The resulting transcript with partial self-complementarity can fold intramolecularly to form dsRNA and can efficiently trigger DNA hypermethylation of homologous sequences *in trans*. If the transcribed IRs contain promoter sequences, hypermethylation of homologous promoters is observed, which can result in stable transcriptional silencing of the affected gene(s) (Mette *et al.*, 2000; Aufsatz *et al.*, 2002a). This observation led to the design of diverse RdDM-reporter systems making use of natural occurring as well as engineered inverted repeats for forward and reverse genetic screens for “silencing suppressor” mutations (Aufsatz *et al.*, 2002b, Fischer *et al.*, 2008, Brosnan and Voinet, 2010, Finke *et al.*, 2012a, Finke *et al.*, 2012ba, Eun *et al.*, 2012)

The RdDM pathway at endogenous target sequences is assumed to be a circular, self-perpetuating mechanisms depending on the transcriptional activity of two plant specific DNA-DEPENDENT RNA POLYMERASES (Pol), Pol IV and Pol V. (Herr *et al.*, 2005; Onodera *et al.*, 2005; Kanno *et al.*, 2005; Pontier *et al.*, 2005).

RdDM is thought to be initiated upon the synthesis of single-stranded long non-coding RNAs (lncRNA) by a complex consisting of Pol IV, a 12-subunit DNA-dependent RNA

polymerase and accessory proteins SAWADEE HOMEODOMAIN HOMOLOG 1 (SHH1), REDUCED IN DNA METHYLATION 4 (RDM4), an *A. thaliana* homolog of yeast *lwr1* and the SWI2/SNF2 chromatin remodeling factor CLASSY1 (CLSY1) (Smith *et al.*, 2007; He *et al.*, 2009; Kanno *et al.*, 2009; Law *et al.*, 2011).

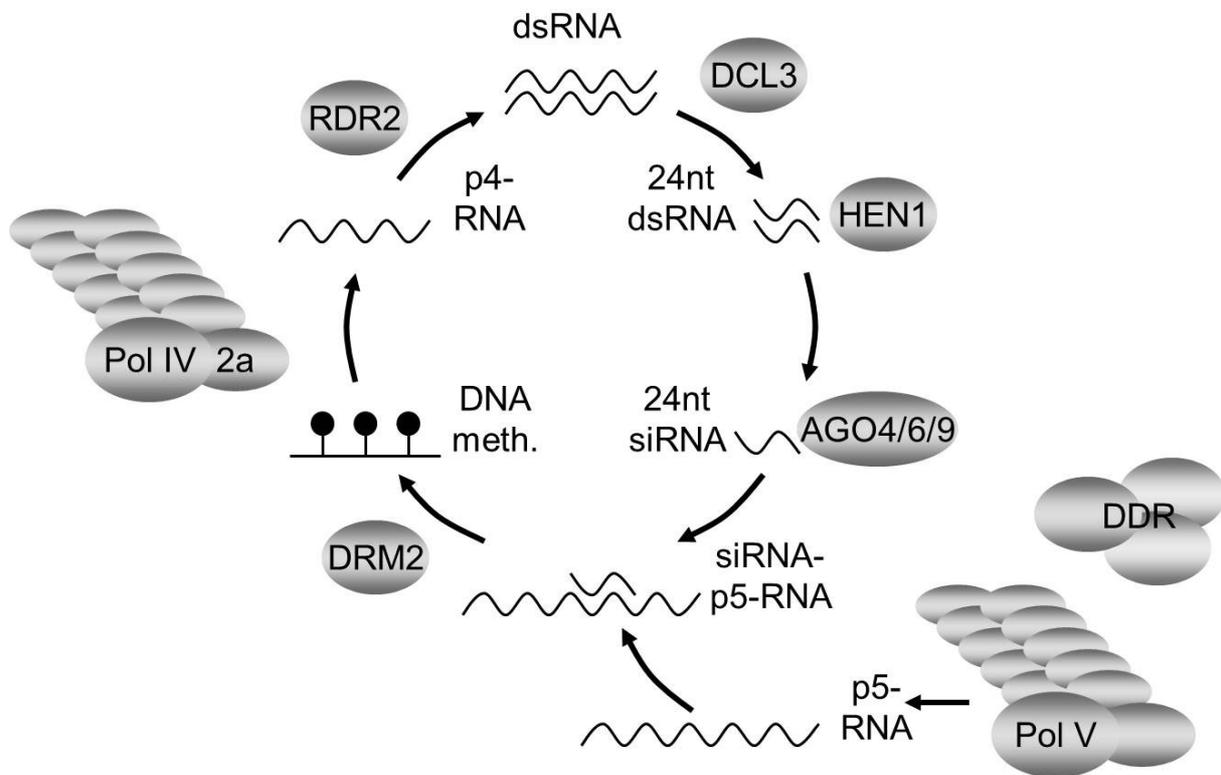

Figure 2: Core components of the RNA-directed DNA methylation pathway

These p4-RNAs are converted into long dsRNAs by RNA DEPENDENT RNA POLYMERASE 2 (RDR2) (Xie *et al.*, 2004; Chan *et al.*, 2004; Law *et al.*, 2011). The dsRNA is then processed by RNaseIII-like endonuclease DICER-LIKE 3 (DCL3) into fragments of 24 nt length with 2 nt 3'-overhangs (Xie *et al.*, 2004; Chan *et al.*, 2004). After 2'-O-methylation of the 3' terminal nucleotides by HUA ENHANCER 1 (HEN1) to prevent polyuridylation and thus, presumably, degradation (Chen *et al.*, 2002; Yu *et al.*, 2005, He *et al.*, 2009, Li *et al.*, 2005; Abe *et al.*, 2010), one of the two strands is incorporated into an ARGONAUT (AGO) protein of the AGO4-clade of *A. thaliana* (AGO4, AGO6, AGO9) to form a silencing effector complex that is recruited to chromatin. AGO4, AGO6 and AGO9 display preferential binding of 24nt siRNAs with an 5' A (Zilberman *et al.*, 2003; Zheng *et al.*, 2007; Vaucheret, 2008; Takeda *et al.*, 2008; Havecker *et al.*, 2010, Eun *et al.*, 2011).

DNA methylation *via* the RdDM pathway further requires activity of Pol V which synthesizes a further class of lncRNAs (Wierzbicki *et al.*, 2008; Wierzbicki *et al.*, 2009;

Wierzbicki *et al.*, 2012). The synthesis of these p5-RNAs depends on the SNF2/SWI2 chromatin remodeling factor DEFECTIVE IN RNA-DIRECTED DNA METHYLATION 1 (DRD1), the SMC-like protein DEFICIENT IN MERISTEM SILENCING 3 (DMS3)/INVOLVED IN DE NOVO 1 (IDN1) and the small, single stranded DNA-binding protein REDUCED IN DNA METHYLATION 1 (RDM1) (Kanno *et al.*, 2004; Kanno *et al.*, 2005; Kanno *et al.*, 2008; He *et al.*, 2009; Ausin *et al.*, 2009; Gao *et al.*, 2010). These proteins are the known constituents of the DDR complex, which interacts with Pol V *via* binding of DRD1 and DMS3 to its largest subunit NRPE1 and presumably recruits Pol V to chromatin (Wierzbicki *et al.*, 2008; Wierzbicki *et al.*, 2009; Law *et al.*, 2011). Recently, DEFECTIVE IN MERISTEM SILENCING 11 (DMS11)/ARABIDOPSIS MICROCHIDIA 6 (AtMORC6) and AtMORC1 were identified as further factors in RdDM suppressor screens. Due to its interaction with DMS3 *in vitro*, DMS11/AtMORC6 is supposed to be part of the the DDR complex. (Lorkovic *et al.*, 2012; Moissiard *et al.*, 2012).

The sequence-specific recruitment of the siRNA-AGO4 complex to the DNA involves base pairing of the siRNA with p5-RNA. Furthermore, protein-protein interactions of AGO4 with SUPPRESSOR OF TY INSERTION 5-LIKE (SPT5L) / KOW DOMAIN CONTAINING TRANSCRIPTION FACTOR 1 (KTF1) and the C-terminus of the large subunit of Pol V, NRPE1, are necessary (Wierzbicki *et al.*, 2008; Wierzbicki *et al.*, 2009; Bies-Etheve *et al.*, 2009, He *et al.*, 2009; Huang *et al.*, 2009). This interaction depends on the presence of the recently defined glycine-tryptophane/tryptophane-glycine (GW/WG) motif (also known as AGO-hook) (El-Shami *et al.*, 2007; Azevedo *et al.*, 2011; Karlowski *et al.*, 2010). The loss of p5-transcripts, as observed in Pol V deficient *nrpe1* mutants, does affect the localization of the siRNA-AGO complex and local DNA methylation patterns, but does not severely decrease the overall genome-scale DNA methylation level. Instead, DNA methylation is relocated, indicating a guiding rather than catalytically activating function of p5-RNAs in RdDM (Wierzbicki *et al.*, 2012). INVOLVED IN DE NOVO 2 (IDN2) as well as FACTOR OF DNA METHYLATION (FDM) 1 to 5 form a family of SUPPRESSOR OF GENE SILENCING 3 (SGS3)-like RdDM factors able to bind dsRNA with 5' overhang. By this, they are implicated in stabilizing the siRNA:p5-RNA duplex (Ausin *et al.*, 2009; Zheng *et al.*, 2010; Xie *et al.*, 2012; Zhang *et al.*, 2012, Finke *et al.*, 2012b). DRM2, and in early developmental stages DRM1, are recruited to chromatin by an unresolved mechanism to confer DNA methylation, which finally causes transcriptional gene silencing in a yet unidentified manner. In analogy to the essential role of SRA domain containing VIM proteins and SUVH4/SUVH5/SUVH6 in the maintenance of CG and CHG context methylation, respectively, propagation of CHH

methylation depends on the partially redundant activity of SUVH2 and SUVH9 (Johnson *et al.*, 2008; Kuhlmann *et al.*, 2012).

1.4 DNA METHYLATION AND THEN...?

While significant progress has been made in deciphering the pathways leading to DNA methylation, the downstream mechanisms responsible for the recognition and interpretation of methylation that finally lead to transcriptional suppression are poorly understood. However, few proteins potentially involved were identified.

Mutations in MORPHEUS MOLECULE 1 (MOM1), a multimerizing CMM domain-containing protein evolved from a CHD3-like (CHROMODOMAIN-HELICASE-DNA binding) SNF2 chromatin remodeling factor, are accompanied by a release of transcriptional repression. DNA methylation is not or only very slightly reduced at loci released in *mom1* (Woodage *et al.*, 1997; Amedeo *et al.*, 2000; Steimer *et al.*, 2000; Habu *et al.*, 2006, Vaillant *et al.*, 2006 Caikovski *et al.*, 2008; Habu *et al.*, 2010; Yokthongwattana *et al.*, 2010; Nishimura *et al.*, 2012). Moreover, release of transcription of gene *SDC* in *mom1* is accompanied by reduced amounts of H3K9me2 (Numa *et al.*, 2010). Although the precise molecular function of MOM1 is still elusive, these results imply an activity downstream of the establishment of DNA methylation. Like MOM1, PICKLE (PKL) is a CHD3-like protein which is involved in transcriptional repression during embryogenesis and in meristematic tissue (Eshed *et al.*, 1999; Ogas *et al.*, 1999; Perruc *et al.*, 2007). Caikovski *et al.*, (2008) observed an additive accumulation of TE-derived *TSI* transcripts in *mom1 pkl* double mutants, pointing to a partially redundant role of both proteins.

Further components that might confer silencing after DNA methylation are methylcytosine binding proteins that contain a SRA or a methylcytosine-binding domain (MBD). While the involvement of SRA-domain containing proteins in DNA methylation-dependent silencing was shown in genetic screens, the role of MBD-proteins in *A. thaliana* is less well understood. MBD proteins are capable to bind DNA methylated in CG and CHH context and their interaction with DDM1 and histone deacetylases, as well as the co-localization with chromocenters and 5s rDNA clusters have been shown (Ito *et al.*, 2003; Zemach and Grafi, 2003; Schebba *et al.*, 2003).

1.5 THE ROLE OF DNA METHYLATION IN PHYSIOLOGICAL PROCESSES

Beside its involvement in epigenetic effects in the strict sense, that is, in setting up mitotically and meiotically heritable differential states of gene expression in phenomena such as TE silencing, imprinting and paramutation, dynamic DNA methylation might play a role in the reaction of plants to environmental factors. Recent studies point to vital functions of DNA methylation in the defense against pathogens. For example, *A. thaliana* plants deficient for functional *Pol V*, *AGO4*, *DRD1*, *RDR2*, *DRM2*, *DRD1* and *MET1* were found to have altered responses to pathogens *Pseudomonas syringae* DC3000, *Botrytis cinerea* and *Plectosphaerella cucumerina* (Agorio and Vera, 2007; Lopez *et al.*, 2011). This is in agreement with altered DNA methylation patterns observed in promoters of pathogen-responsive gene before and after pathogen exposure (Lopez and Vera, 2007; Downen *et al.*, 2012). Furthermore, important functions of DNA methylation mechanisms in response to different abiotic stresses such as heat, high salinity and mutagenic compounds were detected in several studies. For example, activation of the TE *AtCOPIA78/ONSEN* by heat treatment persisted longer in *nrpe1* mutant plants than in wild type individuals and only in the progeny of *nrpe1* plants new *AtCOPIA78/ONSEN* insertions were observed (Ito *et al.*, 2011). Moreover, Trigger *et al.*, (2012) observed the RdDM-regulated transcriptional inactivation of genes important for stomata development as response to low relative humidity. Also, an altered response to DNA-damaging agent methyl methanesulfonate and high salt concentrations was reported for *ddm1* mutants (Yao *et al.*, 2012). The analysis of recombination during meiosis in three complementing studies revealed that in *ddm1* and *met1* plants, recombination frequencies in general stayed similar. However, the distribution of recombination points changed, leading to elevated recombination in pericentromeric regions (Melamed-Bessudo and Levy, 2012; Mirouze *et al.*, 2012; Yelina *et al.*, 2012). This indicates a function of DNA methylation in the regulation of recombination as well.

1.6 SCOPE OF THIS THESIS

The aim of this work was the isolation, identification and genetic characterization of new genes involved in the RdTGS pathway of *A. thaliana* (RdTGS factors) to further refine the knowledge about the mechanisms responsible for RdTGS. To achieve this genes, a transgenic silencing reporter system was used. In this system, the constitutive transcription of an inverted repeat (IR) of the *NOPALINE SYNTHASE* promoter (*ProNOS*) sequence (referred to as *ProNOS-IR*) in the *SILENCER (H)* transgene confers siRNA-dependent *in trans* hypermethylation of an unlinked *ProNOS* copy in an *TARGET (K)* transgene (referred to as *TARGET-ProNOS*). This hypermethylation causes transcriptional inactivation of a *NEOMYCINE PHOSPHOTRANSFERASE II* gene (*NPTII*) under the control of the *ProNOS*, rendering *H* and *K* positive plants sensitive to the aminoglycoside antibiotic kanamycin (Kan^{S}).

To isolate new RdTGS factors a forward genetic screen was performed. The M_2 populations of ethylmethan sulfonate (EMS) treated seeds, homozygous for both transgenes were screened for plants that show a kanamycin resistance (Kan^{R}) phenotype. The obtained lines should be analyzed in respect to the NPTII protein amounts, the DNA methylation of the *TARGET-ProNOS* as well as of several endogenous sequences. Finally, the mutated gene loci causative for the release of RdTGS should be identified by map based cloning.

In a previously performed similar screen, several copies of the targeted T-DNA-construct were present in the genome (Aufsatz et al., 2002). By contrast, the release of silencing of a single copy *TARGET* T-DNA insertion particularly susceptible to TGS induced by the *ProNOS-IR* (Fischer et al., 2008) was assayed in the screen performed during work for this thesis.

2 METHODS AND MATERIALS

2.1 CHEMICALS

If not mentioned otherwise, chemicals and devices used in the work for this thesis were purchased from the companies Bio-Rad Laboratories GmbH (Munich, GER), Ducheeffa Biochemie (Haarlem, NL), Eppendorf AG (Hamburg, GER), Carl Roth GmbH + Co KG (Karlsruhe, GER), Abimed GmbH (Langenfeld, GER), Heinemann Labortechnik GmbH (Duderstadt, GER) and Sartorius AG (Göttingen, GER). Buffers and solutions were prepared in bi-distilled water according to standard protocols (Sambrook and Russel, 2001) and autoclaved if necessary. The majority of enzymes were purchased from Fermentas/ThermoFisher (St. Leon Roth, GER), Taq Polymerase was purchased from Promega (Mannheim, GER). Radioactive labeled compounds were purchased from Hartmann Analytic (Braunschweig, GER).

2.2 PLANT MATERIAL AND GROWTH CONDIDITIONS

The *A. thaliana* accessions Columbia-0 (Col-0) and Landsberg *erecta* (*Ler*) were used in all experiments. The transgenic *A. thaliana* line double homozygous for *TARGET* and *SILENCER* transgenes ($K_{chr1-10}/K_{chr1-10};H/H$) has been described previously (Fischer *et al.*, 2008).

For generation of rosette leaf material for molecular analysis *A. thaliana* was cultivated on IPK greenhouse soil mixture (heat treated at 55°C over night) at 21 °C under a 16 h light / 8 h dark (long day) regime for propagation and seed production; and at 21 °C under a 8 h light / 16 h dark (short day) regime For antibiotics resistance tests, seeds were surface-sterilized and germinated under long day regime in environmental growth chambers (Percival Scientific Inc., CLF Laborgeräte, Emersacker, GER) on agar-plates with germination medium (GM) containing appropriate antibiotics. Seeds were stratified in darkness at 4°C for 48 – 72 h before transfer to growth chambers.

2.3 MEDIA

Table 1: Composition of media used for *in vitro* cultivation of *Arabidopsis thaliana*

Medium	Component	per 1L	final conc.
Germination medium (GM) pH 5.7	Murashige & Skoog Salts	2.15 g	0.215 % (w/v)
	sucrose	10 g	1 % (w/v)
	Fe-EDTA	5 ml (200x)	1x
	B5 vitamins	10 ml (100x)	1x
	MES	0.5 g	0.05 % (w/v)
	Bacto-Agar	8 g	0.8 % (w/v)
GM + Kan ²⁰⁰	kanamycin	4 ml (50 g/l)	200 mg/l
GM + Kan ²⁰⁰ Hyg ²⁰	kanamycin	4ml (50 g/l)	200 mg/l
	hygromycin	0,4 ml (50 g/l)	20 mg/l

Table 2: Infiltration medium for *A. thaliana* transformation

Medium	Component	per 1L	final conc.
Infiltration medium	Murashige & Skoog Salts	2.15 g	0.215 % (w/v)
	sucrose	50 g	5 % (w/v)
	B5 vitamins	10 ml	1 % (w/v)
	BAP	4,25 µl (1 mg/ml)	187 nM
	Acetosyringone	1 ml (100 mg/ml)	0.1 % (w/v)
	Silwet L-77 (Lehle Seeds, USA)	250 µl	0.25 % (v/v)

Table 3: Composition of media used for bacteria cultivation

Medium	Component	per 1L	final conc.
LB medium (Bertani 1951)	Tryptone	10 g	1 % (w/v)
	Yeast extract	5 g	0.5 % (w/v)
	NaCl	10 g	170 mM
for Agar plates	Micro Agar	15 g	1.5 % (w/v)
SOB medium (Hanahan 1983)	Tryptone	20 g	2 % (w/v)
	Yeast extract	5 g	0.5 % (w/v)
	NaCl	0.5 g	170 mM
	KCl	10 ml (250 mM)	2.5 mM
	MgCl ₂	5 ml (2 M)	10 mM
	MgSO ₄	5 ml (2 M)	10 mM
SOC medium (Hanahan 1983)	SOB medium + glucose	20 ml (1 M)	20 mM
YEB medium (Miller 1972)	Beef extract	5 g	0.5 % (w/v)
	Yeast extract	2 g	0.2 % (w/v)
	Peptone	5 g	0.5 % (w/v)
	Sucrose	5 g	0.5 % (w/v)
	MgCl ₂ * 6H ₂ O	0.5 g	2 mM
	for agar plates	Micro Agar	15 g

Construction of complementing vectors

pCMBL2

To generate the basic binary vector suitable for complementation experiments in the used transgene system in *A. thaliana*, binary vector *pCMBAR* (pCAMBIA-proMAS-BAR-35ster) was used as a starting point (M.F. Mette, personal communication). A PCR product containing *LacZ* and MCS of plasmid *pGEM-7Zf(-)* was amplified using primers *pGEM7Z-MCS-for* and *pGEM7Z-MCS-rev* (Table 3) and introduced into the unique *PmeI* restriction site of vector *pCMBAR* to obtain vector *pCMBL2*. *pCMBL2* contains unique *AatII*, *ZraI*, *PspXI*, *SciI*, *XhoI*, *XmaI*, *SmaI*, *BstBI*, *HindIII*, *BspEI* and *BstXI* restriction sites suitable for the insertion of DNA fragments with the option for using X-Gal-based blue / white screening of bacterial colonies containing recombinant plasmids.

pCMBL2+ProIDN2:IDN2

A PCR product comprising the wild-type *IDN2* ORF (including 3'UTR) and a region of around 1300 bp upstream of the transcriptional start site was amplified from *A. thaliana* accession Col-0 genomic DNA. Amplification was carried out using 0.5 U PhusionHF polymerase (Thermo Fischer, Langenselbold) in 50 µl volume containing 1x HF Buffer, 0.25 mM dNTPs, 0.75 µM primers *IDN2-clone-for* and *IDN2-clone-rev* (Table 6) and 2 µl of genomic DNA preparation. The primers used introduced XhoI restriction sites at the ends of the PCR product that were suitable for later sub-cloning into *pCMBL2*. PCR products were separated by electrophoresis in 0.8% agarose gels. The band corresponding to the *IDN2* PCR product was cut from the gel and the contained DNA was purified using a QIAquick gel extraction kit (Qiagen, Hilden) and cloned into vector *pSC-A-amp/kan* using a Strataclone PCR cloning kit (Agilent Technologies). The inserts of β-galactosidase-negative clones were sequenced using standard primers *M13-for* and *M13-rev* as well as *IDN2*-specific primers (Table S2). One clone containing the unaltered wild type sequence was further propagated. The *IDN2* gene was excised by XhoI cleavage and cloned into the XhoI restriction site of *pCMBL2* yielding the binary vector *pCMBL2+ProIDN2:IDN2* suitable for complementation tests by *Agrobacterium tumefaciens* (*A. tumefaciens*)-mediated transformation.

pCMBL2+ProDRM2:DRM2

A PCR product comprising the wild-type *DRM2* ORF (including 3'UTR) and a region of around 450 bp upstream of the transcriptional start site was amplified from *A. thaliana* accession Col-0 genomic DNA. Amplification was carried out using 0.5 U PhusionHF polymerase (Thermo Fischer, Langenselbold) and primers *DRM2-AatII-F* and *DRM2-BspEI-R* (Table 6) in 50 µl volume containing 1x HF Buffer, 0.25 mM dNTPS, 0.75 µM primers *DRM2-AatII-F* and *DRM2-BspEI-R* and 2 µl of genomic DNA to obtain a PCR product flanked by AatII and BspEI restriction sites. The PCR product was purified by agarose electrophoresis, cut from the gel, extracted using QIAquick gel extraction kit (Qiagen, Hilden) and cloned into vector *pSC-A-amp/kan* using a Strataclone PCR cloning kit (Agilent Technologies). The inserts of β-galactosidase-negative clones were sequenced using standard primers *M13-for* and *M13-rev* as well as *DRM2*-specific primers (Table S2). One clone containing the correct wild type *DRM2* ORF was further propagated. The plasmid containing the functional *DRM2* gene as well as vector *pCMBL2* were cleaved using AatII and BspEI. The excised functional *DRM2* gene was

then cloned into vector *pCMBL2* yielding the vector *pCMBL2+ProDRM2:DRM2* suitable for complementation tests by *A. tumefaciens*-mediated transformation.

2.5 *E. COLI* CULTURE AND PLASMID PREPARATION

For bisulfite sequencing analysis 1.5 ml of LB medium supplied with 50 mg/l ampicillin or 50 mg/l kanamycin was inoculated with a single β -galactosidase-negative colony and cultivated over night at 37°C and 200 rpm shaking. Plasmid was isolated using QiaPrep Spin Mini Kit (Qiagen, Hilden) according to the manufacturer's instructions.

For propagation of complementing binary vectors, 5 ml of LB medium supplied with 50 mg/l kanamycin was inoculated with a single colony and cultivated for 6 h at 37°C and 200 rpm shaking. Subsequently 50 ml of LB medium supplied with kanamycin were inoculated with 2 ml of this pre-culture and further incubated over night at 37°C and 200 rpm shaking. Plasmid was isolated using Qiagen Plasmid Midi Kit (Qiagen, Hilden) according to manufacturer's protocol.

2.6 STABLE TRANSFORMATION OF *A. THALIANA* PLANTS

Stable transformation of *A. thaliana* was carried out by *A. tumefaciens*-mediated gene transfer *via* floral dip transformation using *A. tumefaciens* strain pGV2260 (Deblaere *et al.*, 1985; Clough and Bend 1998).

Transformation of *A. tumefaciens* by electroporation

Electrocompetent *A. tumefaciens* cells were obtained using a modified protocol according to Mersereau *et al.*, (1990). LB medium supplied with 20 mg/l rifampicin was inoculated with a single colony of *A. tumefaciens* strain pGV2260 and incubated under shaking at 28°C till the culture reached an OD₆₀₀ of about 0.5. Bacteria were sedimented by centrifugation for 20 min at 5600 x g at 4°C. The resulting pellet was washed twice and finally resuspended in 10 ml of pre-chilled 10% (v/v) glycerin. Aliquotes of 50 μ l of

transformation competent *A. tumefaciens* strain pGV2260 were stored at -80°C until further use.

Prior to transformation into *A. tumefaciens*, DNA was desalted by microdialysis. For dialysis, the solution containing plasmid DNA was spotted on a MF-Millipore membrane (Millipore, Billerica, USA; pore size 0.025 µm) floating on bi-distilled water and incubated for 15 min at ambient temperature. For transformation, 50 µl of electrocompetent *A. tumefaciens* cells were inoculated with 10 µg of desalted plasmid DNA. The suspension was transferred to a pre-chilled electroporation cuvette and two pulses of 2300 mA were applied using a Gene PulserII device (Bio-Rad Laboratories GmbH, Munich). Transfected cells were suspended in 800 µl SOC medium and incubated at 28°C for 1 h. 100 µl of preculture were spread on solid LB medium supplied with 20 mg/l rifampicin and 50 mg/l kanamycin and incubated at 28°C for 48 to 72 h. Appearing colonies were streaked out on solid LB medium containing 50 mg/l kanamycin and in parallel used to inoculate 1.5 ml of LB medium supplied with 50 mg/l kanamycin. Plates and cultures were incubated for 16-20 h at 28°C. A QIAprep Spin Mini Kit (Qiagen, Hilden) was used for plasmid isolation from 10 ml of liquid culture according to the manufacturer's protocol. Presence of the correct insert in the contained plasmid was checked by insert-specific PCR using 1 µl of plasmid solution as template followed by PCR product analysis *via* agarose gel electrophoresis. If products of expected size were detected, the respective *A. tumefaciens* strain was considered suitable for transformation of *A. thaliana*.

Transformation of *A. thaliana*

A. thaliana plants designated for transformation were grown for approximately 4 weeks at long day conditions until onset of flowering.

A single *A. tumefaciens* colony positive for the plasmid was used to inoculate 30 ml of YEB medium supplied with 20 mg/l rifampicin and 50 mg/l kanamycin and incubated in an orbital shaker at 200 rpm and 28°C until an OD₆₀₀ of approximately 0.8. 10 ml each of this culture were used to inoculate two times 200 ml of YEB medium supplied with 50 mg/l kanamycin. After incubation for another 24 h at 200 rpm and 28°C, the bacteria were spun-down for 5 min at 5000 rpm in a Sorvall RC5B centrifuge using rotor Sorvall SH4. Bacteria collected from 400 ml culture were re-suspended in 800 ml infiltration medium containing 0.1 mg/ml acetosyringone. After addition of Silvet L-77 to a final concentration 0.025% (v/v) (Leehle Seeds, Roundrock, USA), stalks of flowering *A. thaliana* plants were submerged in the *A. tumefaciens* suspension. Infiltrated plants

were kept in darkness for 16 h and subsequently cultivated under a long day regime until seed ripening.

To identify primary transformants, T₁ generation plants were screened for BASTA resistance (BASTA^R). Approximately 1.5×10^4 seeds from transformation were germinated on soil under a long day regime. After appearance of the second pair of true leaves, plants were sprayed with 300 μ M BASTA solution. Spraying was repeated after additional five days of cultivation. BASTA^R plants were transferred to small pots and further cultivated under a long day regime until seed ripening. Seeds were harvested from individual plants.

2.7 SURFACE STERILIZATION OF *A. THALIANA* SEEDS

For surface sterilization, *A. thaliana* seeds were incubated for 5 min in 70% ethanol and for 10 min in 8% NaOCl solution. Subsequently, seeds were washed four times in sterile distilled H₂O and resuspended in 0.1% sterile agarose in water.

2.8 DNA EXTRACTION FROM *A. THALIANA* LEAF TISSUE

For 50 to 100 mg fresh weight of leaf tissue, DNA isolation was performed using DNeasy Plant Mini Kit (Qiagen, Hilden, GER), whereas isolation from 500 mg to 1 g was performed using DNeasy Plant Maxi Kit (Qiagen, Hilden, GER) according to the manufacturer's protocol.

2.9 RNA ISOLATION PROCEDURE

For isolation of preparations enriched in "long" and "small" RNAs from of *A. thaliana* leaves, a two-step procedure employing columns of the Qiagen RNeasy Maxi and Qiagen RNeasy Midi Kits were used according to a modified version of the protocol "Purification of miRNA from animal and plant tissues using RNeasy Lipid Tissue Kit and RNeasy MinElute Cleanup Kit" provided by the manufacturer. Plants were grown for 8 weeks under a short day regime.

Isolation of "long" RNAs and reverse transcription-PCR

For isolation of "long" RNAs, approximately 500 mg of leaf material were flash frozen in liquid nitrogen and ground by vortexing for one minute after addition of five grinding spheres (Roche Diagnostics, Mannheim). The material was re-suspended in 15 ml of TRIzol reagent (Invitrogen GmbH, Karlsruhe) or QIAzol reagent (Qiagen, Hilden) and mixed by vortexing at room temperature for one minute. The resulting suspension was

transferred into Corex 30 ml glass centrifugation tubes (Thermo Fisher Scientific, Langenselbold). After adding 3 ml of chloroform, the tubes were sealed with Parafilm M (Brand GmbH, Wertheim), vortexed for one minute at ambient temperature and centrifuged for 30 minutes at 8140 x g at 4 °C in a Sorvall RC5B Plus centrifuge (Thermo Fisher Scientific, Langenselbold). The upper, polar phase (V_1) was transferred to a 50 ml centrifugation tube and mixed with 1 time V_1 of 80% ethanol. The mixture was transferred to an RNeasy Maxi Kit column and centrifuged for five minutes at 2780 x g at 20 °C. The flow-through (V_2) was saved for “small” RNA preparation and stored on ice (see below), while the column with bound “long” RNA was washed once with 15 ml of buffer RW1 and twice with 15 ml of buffer RPE. Wash buffer was removed by 5 min of centrifugation at 2780 x g and room temperature. RNA was eluted by incubation in 1.2 ml of RNase free water and centrifugation at 2780 x g for 5 min. The RNA concentration was determined spectrophotometrically using a Nanodrop ND-1000 (PeqLab, Erlangen).

Isolation of “small” RNAs

The flow-through of the RNeasy Maxi Kit column (V_2 , see above) was transferred to a new vessel, mixed with 1.4 times V_2 of 100% ethanol and applied to an RNeasy Midi Kit column by consecutive centrifugations for 5 minutes at 2780 x g at 20 °C. The column with bound “small” RNA was washed twice with RPE buffer. Remaining buffer was removed by an additional centrifugation step. Subsequently, 250 μ l of RNase free water (V_E) were added and the column was centrifuged for 5 min at 2780 x g at 20 °C. After elution, the RNA concentration was determined using an Ultrospec 3100pro UV/Vis spectrophotometer.

The eluted “small” RNA was precipitated by addition of 0.11 times V_E of 3 M sodium acetate (pH 5.2) and 2.5 times V_E 100% ethanol and subsequent incubation at -20 °C for at least 12 hours. Precipitated RNA was collected by centrifugation for 5 minutes at 18000 x g at 4 °C. The supernatant was removed and the sedimented RNA was washed once in 70% ethanol and dried under vacuum at room temperature for 30 minutes. Finally, the isolated “small” RNA was dissolved in 25 μ l of RNase-free water and stored at -20 °C until further use.

2.10 REVERSE TRANSCRIPTION PCR

For cDNA synthesis, possibly contaminating genomic DNA was fragmented with DNaseI (Fermentas, St. Leon - Rot) at 37 °C for 30 min. The reaction was stopped by adding 1 μ l 25 mM EDTA and incubation for 10 min at 65 °C. 1 μ g of RNA was reverse-transcribed

using a RevertAid H Minus first strand cDNA synthesis kit (Fermentas, St. Leon - Rot). 1 µl of the reverse transcription reaction were used as template for subsequent amplification by PCR using specific primer pairs (Table 7).

2.11 QUANTIFICATION OF *PRONOS* siRNAs

Small RNA northern Blots

For denaturing polyacrylamide gel-based separation of "small RNA" (Mette *et al.*, 2005), 25 µl of RNA gel loading buffer II (Life Technologies GmbH, Darmstadt) were added to the 25 µl of "small" RNA preparation. In addition, NEB microRNA marker (NEB, Frankfurt am Main) containing RNAs of 17 nt, 21 nt and 25 nt length was included as size standard. The mixtures were incubated at 95°C for 5 min and then submitted to electrophoretic separation (800 V; maximum 10 W) for approximately 60 min on 15% polyacrylamid gels containing 7 M urea. After electrophoresis, the gels were incubated in 0.5 x TBE buffer supplied with 1 µg/ml ethidium bromide for 10 minutes and then washed in 0.5 x TBE without ethidium bromide for 20 min. Equal loading of lanes with RNA was checked under UV illumination.

Separated RNAs were transferred to Zeta-Probe GT nylon membranes (Bio-Rad Laboratories, Munich) using a Trans-Blot SD Semi-Dry Transfer Cell (Bio-Rad Laboratories, Munich). From anode to cathode, 3 sheets of 3 MM GB003 blotting paper soaked with 0.5 x TBE buffer, a 0.5 x TBE buffer-wetted sheet of cut-to-size nylon membrane, the polyacrylamide gel and again 3 sheets of 3MM GB003 blotting paper soaked with 0.5 x TBE buffer were set up. Transfer was carried out at 10 V for 1 h in a cold lab. Subsequently, the membrane was rinsed in 0.5 x TBE and the transferred RNA was crosslinked to the membrane by incubation in vacuum at 80°C for 2 h.

Preparation of template DNA for probe synthesis by *in vitro* transcription

Plasmid DNA containing the *ProNOS* template sequence downstream of a T7 promoter was cleaved overnight in a 200 µl reaction with restriction enzyme BamHI (Fermentas, St. Leon - Rot) at 37°C. After restriction cleavage, the plasmid DNA was purified by

phenol-chloroform extraction. 300 µl of Tris/HCl saturated phenol-chloroform-isoamylalcohol were added and mixed with the restriction setup by vortexing for 1 min. Phase separation was achieved by centrifugation for 5 minutes at 18600 x g and 8°C. Phenol-chloroform extraction was repeated once. Subsequently, 300 µl of chloroform were added, mixed with the aqueous phase by vortexing for 1 min and centrifuged for 5 min at 18600 x g at 8°C. The aqueous phase was transferred to a new reaction tube. Plasmid DNA was concentrated by ethanol precipitation, dried under vacuum and dissolved in 50 µl of RNase-free water.

Radioactive labeling of RNA probes.

The *ProNOS* sense siRNA-specific probe was labeled by *in vitro* transcription. 1 µg of template DNA, 2 µl 10x transcription buffer, 1.5 µl of *rNTPs* (rATP, rCTP, rGTP) (6.7 mM each), 1 µl 0.2 M DTT, 1 µl Ribolock RNase inhibitor (Fermentas, St. Leon -Rot), 1 µl T7 polymerase (Fermentas, St. Leon -Rot) and 12.5 µl of [α -³²P] UTP (Hartmann Analytic, Braunschweig) were combined and incubated for 2 h at 37°C. The DNA template was fragmented by addition of 10 U of RNase-free DNase I and further incubation at 37°C for 15 min. After addition of 300 µl Na₂CO₃/NHCO₃ (120 mM/80 mM) and incubation for 2.5 h at 60°C for random RNA fragmentation, 20 µl of 3M NaOAc/HOAc (pH 5.0) were added for neutralization.

Radioactive labeling of mir167 probe

Radioactive labeling of the miR167 DNA oligonucleotide (5'-TAGATCATGCTGGCAGCTTCA-3') probe (Wu *et al.*, 2006) was carried out using T4 Polynucleotide Kinase (Fermentas, St. Leon - Rot) according to manufacturer's protocol.

Hybridization and detection of small RNAs

For detection of *ProNOS* sense siRNA, the membrane with transferred "small" RNA was pre-hybridized with 40 ml hybridization solution at 42°C for at least two h. After pre-hybridization, the hybridization solution was replaced and 300 µl of freshly prepared ³²P-labeled RNA probe was added. Hybridization was performed at 42°C overnight and the membrane was washed two times (15 min each) in buffer containing 2 x SSC/0.2% SDS at room temperature. The membrane was wrapped in plastic foil and exposed to X-ray film with intensifier screen for 1, 4 and 7 days at -80°C.

For re-hybridization of membranes with a miR167 specific probe, the hybridized *ProNOS*-specific probe was stripped of by brief washes in buffer containing 0.1 x

SSC/0.5% SDS at 95 °C. The stripped membranes were pre-hybridized with hybridization buffer according to Church and Gilbert for 16 h at 42 °C. Subsequently, the labeled DNA oligonucleotide probe was added and allowed to hybridize for 24 h at 42 °C. The blot was washed in 2 x SSC containing 0.2% SDS and exposed to X-ray film with intensifier screen for 3 days at -80 °C.

2.12 DNA METHYLATION ANALYSIS

Analysis by methylation-sensitive restriction cleavage

For *TARGET-ProNOS* methylation analysis, approximately 50 ng of DNA extracted from adult leaves of 8-week-old plants grown under short day regime were dissolved in 400 µl of distilled water, 50 µl of 10x Tango buffer and 50 µl of bi-distilled water were added to a final volume of 500 µl. Aliquots of 100 µl were incubated with 10 U of restriction enzymes Psp1406I, NheI, Alw26I, NcoI (Fermentas, St. Leon –Rot) or without restriction enzyme, respectively, and incubated at 37 °C for 16 h. Subsequently, the restriction enzymes were heat-inactivated by incubation for five minutes at 85 °C. 399 µl of bi-distilled water were added to a final volume of 500 µl. Quantitative PCR was performed using an iCycler IQ device (Bio-Rad Laboratories GmbH, Munich). 12.5 µl of SYBR Green Supermix (Bio-Rad Laboratories GmbH, Munich) and 1.25 µl of primers *ProNOS-top-F* and *ProNOS-top-R* (final concentration 0.25 µM each) were added to 10 µl of cleaved DNA or control DNA templates, respectively, to reach a final volume of 25 µl for each sample. The PCR was performed using the following temperature regime:

Temperature	Duration	Cycles
95 °C	5 min	1
95 °C	15 sec	40
62 °C	30 sec	
72 °C	30 sec	
Data acquisition		
72 °C	5 min	1

PCR was calibrated using logarithmic serial dilutions from 10^{-2} to 10^{-5} of genomic DNA preparations. The threshold cycle (C_t value) for reactions with serial dilution samples was determined in technical duplicates. C_t values of reactions with cleaved and control DNA samples were determined in duplicate. Samples with mean C_t values ± 0.25 cycles were included in calculations. Data analysis was performed using the $\Delta\Delta C_t$ method (Pfaffl, 2001). Results are presented as percent of the mean signal obtained for the control samples without restriction enzyme (set to 100%).

For methylation analysis of *IGN5A*, *IGN23* and *IGN25* sequences, 0.05 µg of genomic DNA was dissolved in 25 µl bi-distilled water and 5 µl of Buffer R and 20 µl of bi-distilled water were added to a final volume of 50 µl. After addition of 10 U of restriction enzyme BsuRI/HaeIII (Thermo Fischer, Langensfeld), the reaction was incubated for 16 h at 37°C. Subsequently, the reaction was incubated for 5 min at 85°C for restriction enzyme inactivation.

PCR was performed in a reaction volume of 25 µl in an Eppendorf MasterCycler Gradient device (Eppendorf, Hamburg) using GoTaq Flexi Polymerase (Promega, Mannheim). 14.4 µl bi-distilled water, 5 µl of GoTaq Flexi Polymerase Buffer, 3 µl of 25 mM MgCl₂ (final concentration: 3 mM), 0.5 µl 10 mM dNTPs (final concentration: 0.2 mM), 0.5 µl of template specific forward and reverse primer (Table 7) (final concentration 0.2 µM each) and 1.25 U GoTaq Flexi polymerase were combined and added to 1 µl of restricted template DNA. PCR reaction was performed using the following temperature regime: 5 min 95°C, 35x (15 sec 95°C, 10 sec 61°C, 20 sec 72°C). Amplification of *ING22*, a sequence lacking a HaeIII cleavage site, was used as loading control.

Bisulfite sequencing

For methylation analysis by bisulfite-mediated conversion of unmethylated cytosines into uracil, approximately 0.15 µg of genomic DNA extracted from leaves of 8-week-old plants grown under short day conditions were bisulfite-treated using an Epitect Bisulfite Kit (Qiagen, Hilden) following the protocol “Sodium Bisulfite conversion of unmethylated cytosines in DNA from Low-concentration solution (Version 2009)” provided by the manufacturer.

For PCR amplification of target sequences, GoTaq Flexi DNA polymerase (Promega, Mannheim) was used. Reaction was carried out in a volume of 50 µl containing 10 µl of 5x GoTaqGreen Flexi buffer, supplied with 3 mM MgCl₂, 0.2 mM dNTPs, 0.2 µM of respective forward and reverse primers and 1 U of GoTaq polymerase. 1 µl of converted DNA was used as template for amplification. Primers used for amplification of *TARGET ProNOS*, *AtSN1*, *MEA-ISR*, *AtMU1*, *AtCOPIA4*, *IGN5A*, *IGN23* and *BASHO210* regions are listed in Table 9.

PCR products were purified using QIAquick PCR Purification Kit (Qiagen, Hilden), cloned into vector pSC-A and transferred into Strataclone Solo Pack competent cell using the Strataclone PCR cloning kit (Agilent Technologies, Santa Clara, USA) according to manufacturer's protocol. After recovery, transformed cells were spread on LB plates containing either 50 mg/l ampicillin or 50 mg/l kanamycin, IPTG and X-Gal and incubated at 37°C for 16 h. 12 to 24 colonies negative for β-galactosidase activity were used to inoculate 1.5 ml LB medium cultures, which were then incubated for 12 to 16 h at 37°C in an orbital shaker at 200 rpm. Subsequently, a QIAquick SpinMini Kit was used to isolate plasmid DNA.

For validation of the correct insert size, 10 µl of plasmid preparation was restriction-cleaved using 4 U EcoRI and 4 µl Buffer 10x Tango in 20 µl final volume. The reactions were incubated for 3 h at 37°C. Restriction fragments were separated by agarose gel electrophoresis and detected using UV excitation in presence of 1 µg/l ethidium bromide.

Uncleaved plasmid DNA from preparations that had shown a restriction fragment of the expected PCR product size ± 30 bp were Sanger-sequenced by IPK's in-house core facility service.

2.13 PROTEIN QUANTIFICATION

Total protein in the same extracts was determined using a Pierce BCA Protein Assay kit (ThermoFisher, Rockford, USA). 25 μ l of the NPTII ELISA raw extract were added to 500 μ l of BCA working solution and incubated for 30 min at 37°C in a water bath. After incubation, 500 μ l of bi-distilled water were added to every sample and extinction at 592 nm was determined using an Ultrospec 3100pro UV/Vis spectrophotometer (Amersham Bioscience, Freiburg, GER). Extinction values were converted to protein concentration values using a BSA serial dilution in concentration range between 0.125 and 2 μ g/ml as reference.

Amounts of NPTII protein in plant extracts were determined using Agdia PathoScreen Kit for NPTII (Agdia, Elkhart, USA). Rosette leaflets of 8-week-old short-day-grown plants were flash frozen in liquid nitrogen, ground using a swing mill type Retsch MM301 and resuspended in provided protein extraction buffer. All further procedures were performed according to manufacturer's recommendations.

2.14 DEVELOPMENT OF INDEL AND CAPS MARKERS

InDel markers

Initially, PCR-based markers detecting insertion / deletion (InDel) sequence polymorphisms between *A. thaliana* accessions Col-0 and Ler were used to map the positions of mutations induced by EMS. Per chromosome, four InDel markers evenly distributed along the respective chromosome arms were chosen from a set published by Salathia *et al.*, (2008). Selection was according the following criteria:

- Maximal PCR product size: 1000 bp
- Minimal size difference of products from Col-0 compared to Ler: 25 bp
- Maximal size difference of products from Col-0 compared to Ler: 500 bp

Prior to application in mapping procedure, InDel markers were tested with DNA from Col-0 and Ler plants for reliability. The PCR primers used and the sizes of resulting PCR products are indicated in Table S3.

CAPS marker

Cleaved amplified polymorphisms (CAPS)-based markers were developed based on single nucleotide polymorphisms (SNPs) between *A. thaliana* accessions Col-0 and Ler annotated in the TAIR database (versions TAIR 8 to10). Col-0 and Ler sequence were checked for suitable restriction sites using software webcutter 2.0 (rna.lundberg.gu.se/cutter2/).

Prior to application in mapping procedure, CAPS markers were tested with DNA from Col-0 and Ler plants for reliability. The PCR primers, the appropriate restriction enzymes, the sizes of resulting PCR products and restriction fragments are indicated in Table S5.

2.15 ILLUMINA VERACODE GOLDEN GATE ASSAY

Development of the 48-plex assay

For the Illumina Veracode GoldenGate assay (GoldenGate assay) 47 SNPs variant between accessions Col-0 and Ler, were chosen based on a set of published SNP marker suitable for multiplexed genotyping (Kover *et al.*, 2010). Markers were chosen according to criteria provided by Illumina Inc. (www.illumina.com/documents/products/technotes/technote_goldengate_design.pdf).

At first, 60 bp of flanking sequence on either side of chosen SNPs were checked for additional variant positions using sequence information of two publicly available databases (www.arabidopsis.org TAIR 9.0 and www.signal.salk.edu/atg1001.htm). SNPs with flanking sequences that contained additional polymorphisms in this range according to one of these databases were excluded from further consideration. As second selection criterion, the threshold for the “minimum SNP specific score” as calculated by Illumina Inc. according to a confidential algorithm, was set to 0.75 in order to achieve at least three evenly distributed reliable markers per chromosome arm. In addition, one marker specifically targeting the sequence of the *H* transgene was included in the assay. All SNPs included in the GoldenGate assay are listed in Table S4. Tests were performed according to the protocol “GoldenGate genotyping assay for VeraCode – Manual Protocol Rev. B” provided by the manufacturer, without performance of the optional steps “Make qDNA plate” and “Scan qDNA plate”. The obtained data were analyzed using the GenomeStudio software provided by Illumina Inc. according to provided guidelines. Only markers matching a GT-Score of at least 0.6 in the assay output were included in the genotyping analysis.

2.16 NEXT GENERATION SEQUENCING

Next generation sequencing (NGS) of plant genomic DNA was performed by IPK's in-house sequencing facilities using an Illumina HiSeq2000 device according to manufacturer's protocols. Sequencing was performed in paired-end reads. Mapping of obtained reads to the *A. thaliana* reference genome (TAIR10), SNP calling, effect prediction and *de novo* assembly of the *K/K*; *H/H* and mutant genomes was performed by Dipl. math. Martin Mascher, using the Burrow-Wheeler Alignment Tool (<http://bio-bwa.sourceforge.net>, Li and Durbin, 2009) the Sequence Alignment/Map tool (<http://samtools.sourceforge.net/>, Li *et al.*, 2009), snpEff (<http://snpeff.sourceforge.net/>, Cingolani *et al.*, 2012) and CLC assembler (www.clcbio.com), respectively according to established protocols. For identification of mutations in the candidate lines, the respective SNP lists were imported into MS Excel and compared using the Merge Table Wizzard Add-in (<http://www.ablebits.com/excel-lookup-tables/index.php>). SNPs occurring in more than one of the mutant candidate lines were considered as preexisting in the transgenic line submitted to mutagenesis and thus considered as "false positives" and excluded from further analysis. Furthermore, "true positive" SNPs affecting promoters, introns, 5' UTR and 3'UTR as well as such in exons that were expected to cause silent mutations were excluded from searches for mutations plausibly causative for kanamycin resistance.

2.17 MUTAGENESIS

Custom mutagenesis of a line homozygous for *TARGET* transgene *K_{chr1-10}* (briefly *K*) and *SILENCER* transgene (briefly *H*) (Fischer *et al.*, 2008) was performed by Leehle Seeds, Round Rock, Texas, USA. Approx. 100,000 seeds of the F₄ generation were exposed to ethyl methanesulfonate (EMS) and then allowed to germinate on soil in order to obtain approx. 50,000 mutagenized M₁ plants, which were allowed to set seeds by self-pollination. The resulting M₂ seeds were harvested in 32 batches, each batch thus containing the progeny of approximately 1,500 M₁ plants. A sample of the initial F₄ seeds was germinated without EMS treatment under otherwise same growth conditions and the resulting non-mutagenized control (C₁) plants were also allowed to self-pollinate to generate C₂ seeds.

2.18 ESTABLISHMENT OF MAPPING POPULATIONS

To establish mapping populations, M₃ plants of mutants were crossed with the *A. thaliana* accession *Ler*. The success of the crosses was validated in F₁ progeny (M₃F₁)

by qualitative histochemical GUS staining to detect a *Pro35S-GUS* reporter gene present in the *K* transgene. In order to insure the presence of the *K* and *H* transgenes as well as of the mutation in homozygous state, F₂ generation seedlings obtained from these crosses by self-pollination (M₃F₂) were screened for plants showing hygromycin and kanamycin resistance (Hyg^R Kan^R) simultaneously. To rule out possible “false positive” M₃F₂ individuals, approx. 110 plants of M₃F₃ progeny obtained by self-pollination was germinated on GM supplied with kanamycin (200 mg/l) and hygromycin (20 mg/ml). Only M₃F₂ plants that met the expected minimal 56% of Hyg^R Kan^R plants in their respective F₃ progeny were included in the mapping populations. In addition, C₃ non-mutagenized control plants were crossed to *Ler* and resulting C₃F₁ progeny was allowed to self-pollinate. Resulting C₃F₂ generation seeds were screened for Hyg^R plants by germination on GM supplied with 20 mg/l hygromycin. Presence of *H* was validated by qualitative histochemical GUS staining. Resulting C₃F₂ Hyg^R GUS⁺ plants containing *K* and *H* transgenes were used as control mapping population.

Histochemical GUS stain

The β-glucuronidase (GUS) histochemical staining procedure was carried out in 96-well micro titer plates (Greiner Bio-One, Solingen, GER). Two leaf discs of distinct mature rosette leaves were assayed per plant. 200 µl of GUS working solution were added to each well and allowed to infiltrate the leaf disc by application of vacuum for 5 minutes. After incubation for 16 h at 37°C, the GUS working solution was replaced by 200µl of 70% ethanol and incubation for additional 3 h was allowed. This ethanol washing step was repeated until all chlorophyll was removed from leave disks.

Table 10: Solutions used for histochemical GUS staining

Solution	Component	per 10 ml	final conc.
X-Glu solution	X-Glu (5-bromo-4-chloro-3-indolyl-β-glucuronide) in DMFA (N,N-dimethylformamid)	1 g	1% (w/v)
NaN ₃ solution	NaN ₃ in sterile dest. H ₂ O	0,5 g	5% (w/v)
working solution	X-Glu solution	0,5 ml	0,05 % (w/v)
	NaN ₃ solution	0,2 ml	0,1 % (w/v)
	100 mM NaH ₂ PO ₄ / Na ₂ HPO ₄ pH 7.0	9,3 ml	93 mM

2.19 STATISTIC ANALYSIS

To test DNA methylation levels of identified mutant lines determined by bisulfite sequencing for significant differences relative to *K/K;H/H* DNA methylation X² test was used. X² test was also used for statistic analysis of segregation of the homozygous Col-0 allele in mapping populations.

3 RESULTS

3.1 FORWARD GENETIC SCREEN FOR MUTATIONS RELEASING RNA-DIRECTED TRANSCRIPTIONAL GENE SILENCING

Selection of mutants using kanamycin resistance as indicator

In order to identify mutants in which RNA-directed transcriptional gene silencing (RdTGS) of the *ProNOS-NPTII* reporter gene was released, and thus *NPTII* expression was reactivated, approx. 20,000 M₂ seeds per obtained seed batch (see section 2.17) were germinated on growth medium (GM) containing 200 mg/l of kanamycin. All M₂ batches yielded some kanamycin resistant (Kan^R) individuals, while no Kan^R plant was observed in the non-mutagenized C₂ control. From each batch, ten Kan^R M₂ plants (1-1 to 1-10, 2-1 to 2-10, and so on, till 32-1 to 32-10) were transferred to soil and allowed to self-pollinate. Resulting M₃ seeds from individual M₂ were collected and their kanamycin resistance was verified by germinating approx. 200 seeds per M₂ line on GM containing 200 mg/l of kanamycin. This resulted in the identification of 104 Kan^R M₃ lines that showed at least 95% of viable resistant seedlings in the presence of kanamycin. To avoid possible redundant siblings, initially one Kan^R M₃ line per M₂ batch was chosen for characterization.

As the first step of my thesis work, the presence and integrity of the *K* and the *H* transgene in Kan^R M₃ lines was checked by PCR using transgene-specific primer combinations (Table S1). It revealed that all 32 initially selected Kan^R lines contained the *K* transgene, but only a single line contained the *H* transgene (Figure 3B and data not shown). As loss of the *H* transgene *per se* can result in the *ProNOS-NPTII* reactivation (Aufsatz *et al.*, 2002), the presence of both transgenes is a *de regieure* prerequisite for the identification and later map-based cloning of gene loci essential for RdTGS. Thus, so far only Kan^R M₃ line 2-5 was suitable for further work.

To obtain additional candidates suitable for further analysis and map-based cloning, the remaining 72 Kan^R M₃ lines from the first screening were tested for the presence of full length *K* and *H* transgenes using transgene-specific PCR. Five additional lines were found to contain both transgenes and were included in further analysis (Figure 3C).

Selection of mutants using combined hygromycin and kanamycin resistance as indicator

As the above six confirmed Kan^R M₃ lines were rather limited material to work with, it was attempted to isolate further candidate lines by repeating the screening of the M₂ material.

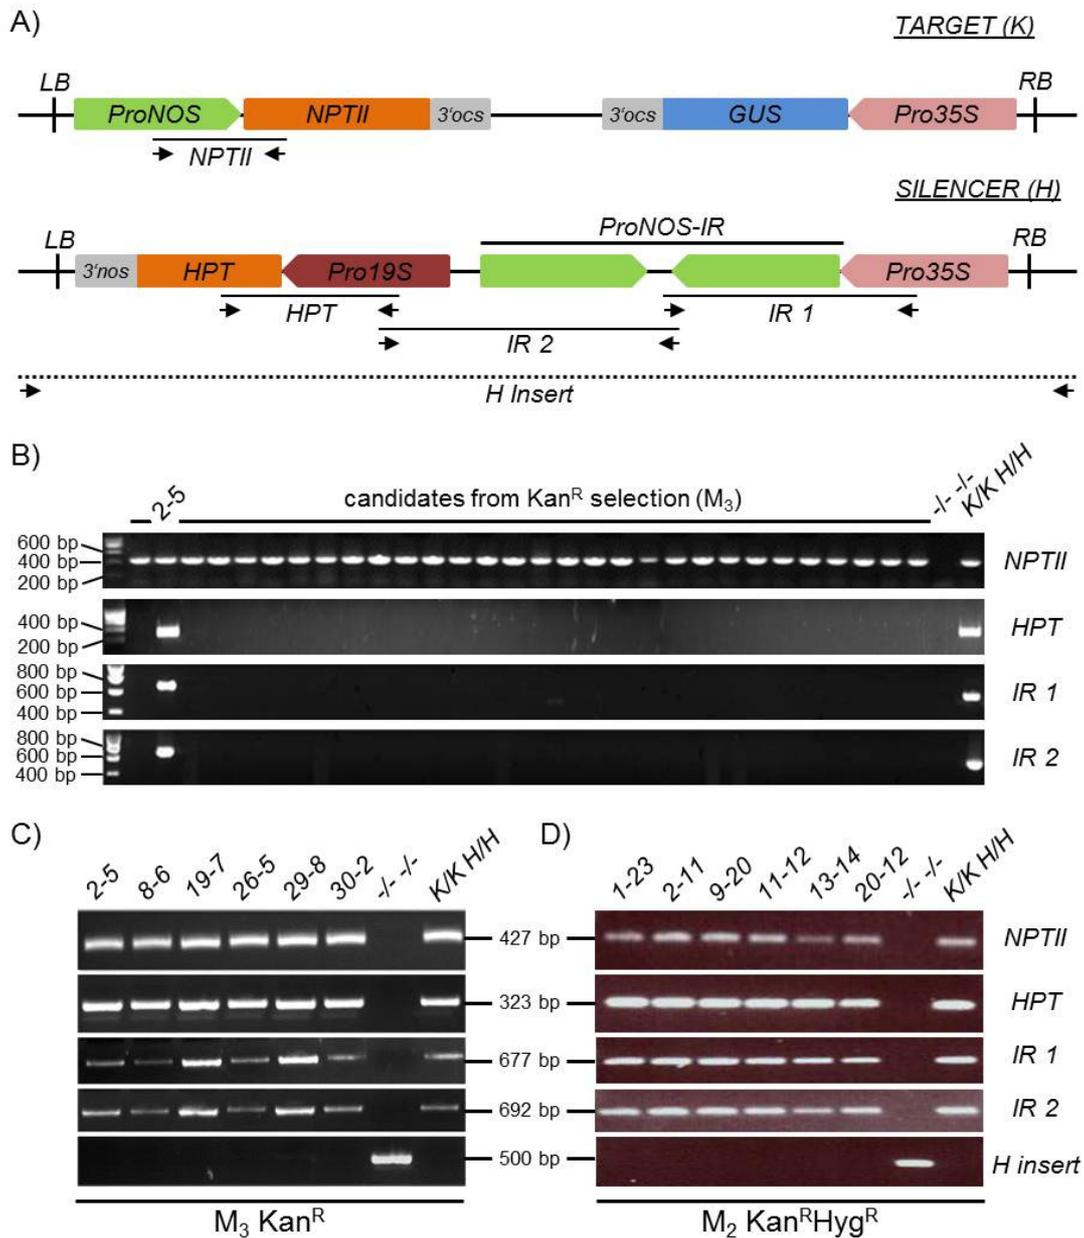

Figure 3: Verification of transgene integrity in candidate mutant lines.

A) Transgene maps. Approximate positions of primers used for transgene-specific PCRs are indicated by arrows. The "H insert" PCR only results in a product when the *H* transgene is absent or heterozygous. B) PCR test for 30 initial mutant candidates derived from the Kan^R screening. C) Transgene integrity in 6 lines showing at minimum 95% Kan^R in M₃ generation obtained from Kan^R selection. D) Transgene integrity in mutant lines obtained from Kan^R Hyg^R selection. PCR tests were performed using genomic DNA of original Kan^R Hyg^R M₂ plants. PCR product sizes are indicated B), C) Five M₃ plants per line were tested to check for segregation of the transgenes, but all gave consistent results.

The result of the first round of screening implied that the seed material submitted to mutagenesis was contaminated with material that has lost the *H* transgene or contained it in a heterozygous manner. Therefore, the majority (98 of 104) of M₂ lines obtained by screening for Kan^R phenotype were “false positive” plants that had lost the *H* transgene by segregation.

As a constitutively expressed *HYGROMYCINE PHOSPHOTRANSFERASE (HPT)* reporter gene that confers hygromycin resistance (Hyg^R) is part of the *H* transgene, presence of the *H* can be selected for by germination on medium containing hygromycin in order to minimize the number of “false positive” Kan^R M₂ plants. Thus, M₂ seed stocks were rescreened for individuals that showed a Kan^R Hyg^R phenotype by germination on GM containing 200 mg/l of kanamycin and 20 mg/l of hygromycin. No Hyg^R Kan^R plant was observed in the non-mutagenized C₂ control.

Surviving seedlings grown on agar medium containing hygromycin and kanamycin showed generally weak root growth. To evaluate whether the direct transfer of Kan^R Hyg^R seedlings to soil was possible or a period of recovery at non-selective agar medium was necessary prior to the transfer, two sets of Kan^R Hyg^R M₂ seedlings, 12 per set, from batch no.1 were transferred either directly to soil (1-11 to 1-22) or first to non-selective medium (1-23 to 1-34). As plant viability was not compromised by the direct transfer to soil, plant recovery at non-selective medium was not further applied. Therefore, the maximum number of transferred Kan^R Hyg^R M₂ plants was reduced to 12 per individual batch (2-11 to 2-22; 3-11 and so on). Transferred plants were tested for the presence of both transgenes via PCR. Approximately 110 M₃ seedlings of every obtained Hyg^R Kan^R M₂ plant were tested for Kan^R on GM supplied with 200 mg/l kanamycin. Thirteen M₃ mutant lines (1-23, 2-11, 9-19, 9-20, 9-21, 11-11, 11-12, 11-13, 13-14, 14-12, 17-13, 18-15, 20-12) that showed at least 95% Kan^R plants were considered suitable and selected for further analysis.

3.2 THE NPTII PROTEIN LEVEL AS CRITERION FOR “NO RNA-DIRECTED TRANSCRIPTIONAL GENE SILENCING” MUTANTS

Amount of NPTII protein in obtained mutant lines

In the transgene system used to perform the genetic screen, compromising of the RdTGS mechanism should result in a release of *NPTII* reporter gene expression. Hence, an increase in NPTII protein as cause for kanamycin resistance should be observed in genuine “*no RNA-directed transcriptional gene silencing*” (*nrd*) mutants. Nevertheless,

Results

studies by others have shown that kanamycin resistance can also arise in *A. thaliana* loss-of-function mutants (Aufsatz *et al.*, 2009; Conte *et al.*, 2009) or gene overexpression lines (Mentewab and Steward, 2005) by affecting chloroplast-localized transporter proteins without any requirement for NPTII expression. Therefore, the amounts of the NPTII protein in relation to the total soluble protein in rosette leaves of mature M_3 plants were determined by ELISA in comparison to control plants grown in parallel (Figure 4).

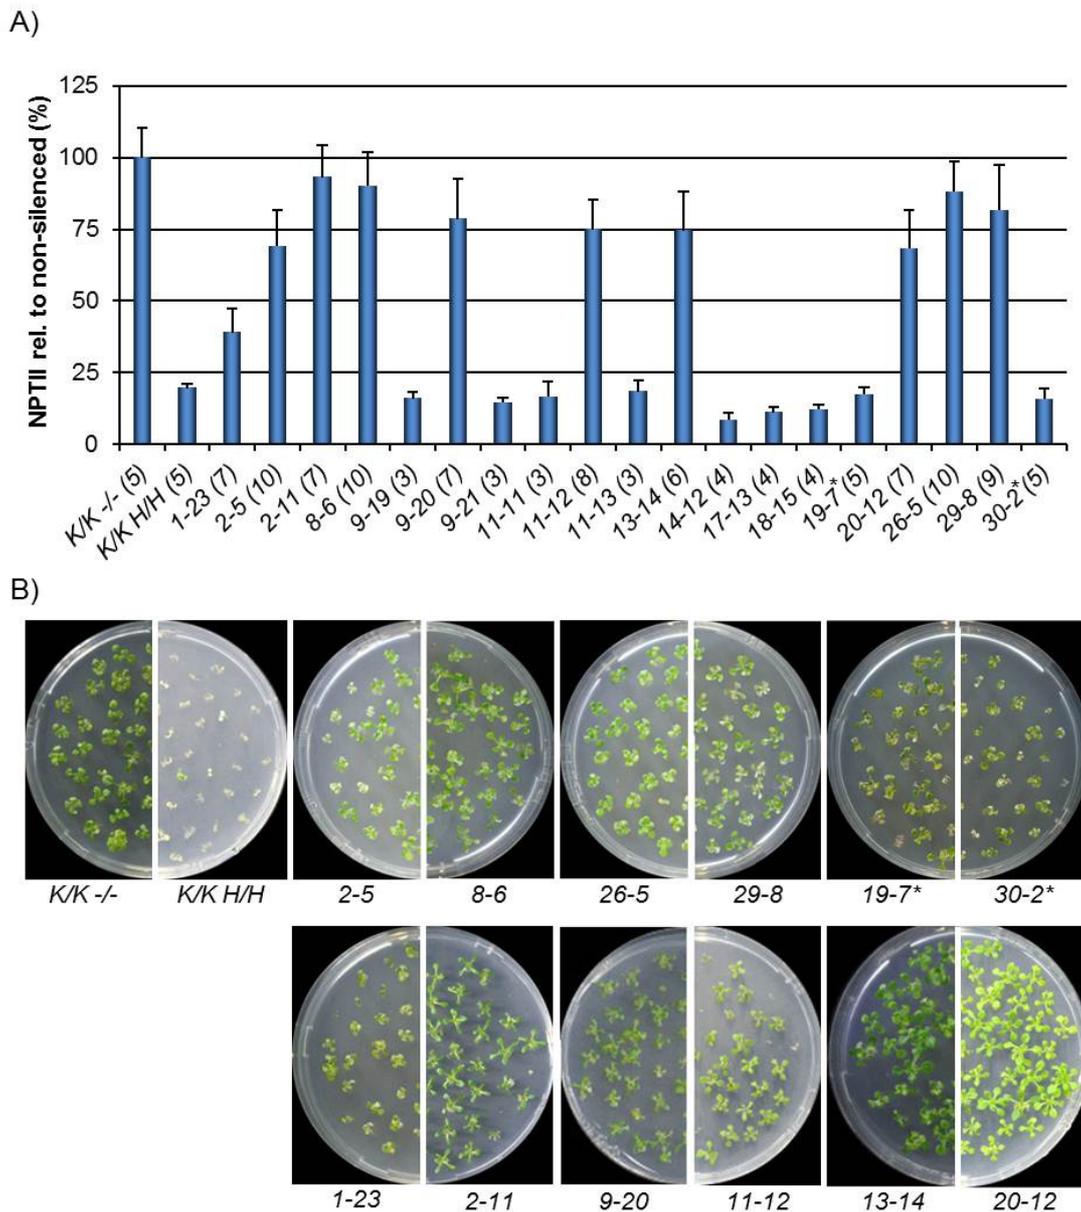

Figure 4: Quantification of NPTII protein levels by ELISA and growth phenotype of M_3 lines

A) Amounts of the NPTII protein were measured in relation to total soluble protein in extracts from leaves of 8-week-old plants. Results are indicated as relative NPTII levels relative to the mean value for non-silenced expression in (*K/K;-/*) plants (set to 100%). Numbers in parentheses indicate numbers of individual M_3 plants tested. The background signal obtained from non-transgenic control plants was subtracted prior to calculation. Column height represents mean values; error bars represent standard deviation. B) M_3 seedlings of mutant lines showing released NPTII expression compared to mutant lines 19-7 and 30-2 displaying NPTII levels as low as wild-type *K/K;H/H* plants on GM supplied with 200 mg/l kanamycin.

The relative NPTII level was found reduced in non-mutagenized wild type plants harboring both (*K/K;H/H*) compared to those that only contained the *K* transgene (*K/K;-/-*), yet not completely abolished. The remaining NPTII might help to explain the high concentration of kanamycin necessary to suppress growth of *K/K;H/H* plants in my work in comparison to a previous study utilizing a similar transgene system involving a *NPTII* reporter gene (Aufsatz *et al.*, 2002a; Aufsatz *et al.*, 2002b; Aufsatz *et al.*, 2004).

M₃ plants from lines 2-5, 8-6, 26-5 and 29-8 from the Kan^R screen and lines 2-11, 9-20, 11-12, 13-14 and 20-12 from the Kan^R Hyg^R screen clearly showed more NPTII protein than *K/K;H/H* plants, almost resembling *K/K;-/-* plants. Line 1-23 showed, however less pronounced, also a release of NPTII. Interestingly, despite their Kan^R phenotype, M₃ plants from lines 9-19, 9-21, 11-11, 11-13, 14-12, 17-14, 18-15, 19-7 and 30-2 did not display a noticeable increase in the NPTII protein compared to wild type *K/K;H/H* plants.

3.3 DNA METHYLATION OF THE *TARGET PRONOS* IN *NRD* MUTANTS

In the majority of suppressor of silencing mutants obtained from genetic analysis of transgene-based TGS in *A. thaliana*, the release of silencing is accompanied by a decrease in DNA methylation at the respective transgene. This can be due to impaired siRNA synthesis, inadequate “interpretation” of the siRNA signal or the inability to conduct the methylation at sites addressed by siRNAs (Aufsatz *et al.*, 2002; Kanno *et al.*, 2005; Zheng *et al.*, 2007). Nevertheless, there are mutants like *mom1*, which can cause release of TGS without affecting DNA methylation (Amedeo *et al.*, 2001).

To test for this, DNA methylation at the *ProNOS* in the *K* transgene (*TARGET-ProNOS*) was analyzed in DNA extracted from rosette leaves of individual mature plants (Figure 5B).

Analysis by methylation-sensitive restriction cleavage

The analysis by cytosine methylation-sensitive restriction cleavage coupled to subsequent quantitative PCR allowed testing of the *TARGET-ProNOS* methylation in DNA from multiple individual plants. It revealed a conspicuous amount of amplifiable, and thus uncleaved, genomic DNA in *K/K;H/H* wild type plants after incubation with Psp1406I (cleavage impaired by methylation in CG context) as well as NheI and Alw26I (for both, cleavage impaired in non-CG context) (Figure 5B). The related recognition sites are inside the region covered by the *ProNOS-IR* transcripts and thus these sites are

methylated (Figure 5A). On the other hand, incubation with NcoI targeting a cleavage site outside of the region covered by the *ProNOS-IR* transcripts resulted in almost complete cleavage of the thus unmethylated DNA.

The genomic DNA from M₃ plants of most mutants depicted a preservation of methylation at the Psp1406I site. The strongest reduction in comparison to *K/K;H/H* plants of the same generation was observed for lines 2-11 and 13-14. Restriction cleavage using NheI and Alw26I indicated low amounts of amplifiable DNA and thus low cytosine methylation at the respective recognitions sites at levels comparable to *K/K;-/-* control plants. Notably, for line 1-23 an intermediate amount of methylation was seen at NheI and Alw26I restriction sites, differing from both, *K/K;H/H* and *K/K;-/-* plants. Consistent with the assumption of persistence of RdTGS of the *NPTII* gene in lines 19-7 and 30-2, DNA methylation resembling the results of *K/K;H/H* wild type plants was observed for all tested restriction enzymes (Figure 5B).

Bisulfite Sequencing

Analysis using methylation sensitive restriction cleavage could test cytosine methylation only at three sites in the *TARGET-ProNOS*. Determination at single base resolution was performed by bisulfite sequencing. The analyzed part of the top strand of the *ProNOS* in the *ProNOS-NPTII* reporter gene included 69 cytosines, 18 in CG, 12 in CHG and 39 in CHH context, respectively (Figure 5C and Figure S1).

In agreement with the results from restriction cleavage, *K/K;-/-* plants displayed only very few unconverted cytosines and thus at best low cytosine methylation. The observed approx. 1 % of “methylated” cytosines might actually result from incomplete chemical conversion of unmethylated cytosines in the employed protocol than represent genuine methylated cytosines. In contrast to *K/K;-/-* plants, *K/K;H/H* individuals, displayed a high level of DNA methylation evenly distributed along the region of the *ProNOS* sequence covered by the *ProNOS-IR* transcripts at cytosines in all contexts. In particular, 83%, 79% and 59% of cytosine in CG, CHG and CHH context, respectively, were found methylated. Methylation in the CG context was only slightly affected in 6 mutant lines from the Kan^R screen and somewhat more reduced in lines from the Kan^R Hyg^R screen. The CHG and CHH context methylation was clearly reduced in all analyzed mutant lines except 19-7 and 30-2. It is noteworthy that, in agreement with the restriction cleavage analysis, line 1-23 displayed a less severe decrease of methylation at cytosines in the CHH context. About 25% of cytosines in the CHH context remained methylated in this line (Figure 5C).

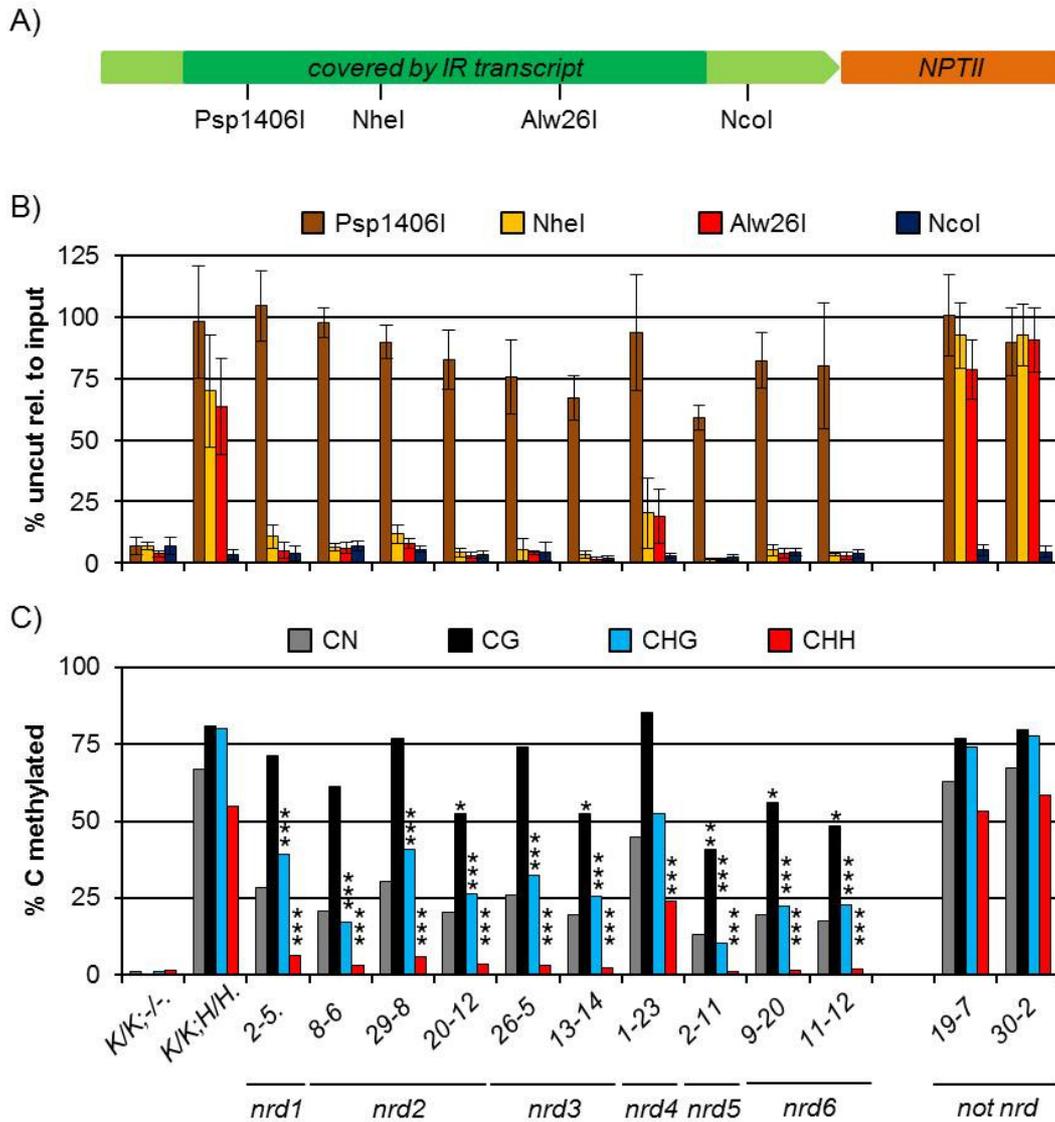

Figure 5: DNA methylation at *TARGET-ProNOS*.

A) Schematic representation and approximal location of the analysed restriction cleavage sites within the *TARGET ProNOS*. B) Cytosine methylation determined by quantitative PCR after cleavage with methylation sensitive restriction enzymes (C in recognition sequence underlined: methylation of cytosine blocks cleavage according to REBASE <http://rebase.neb.com>) Psp1406I (symetric CG context AACGTT, NheI (CHG and CHH context: GCTAGC), Alw26I (CHH context: GTCTC, GAGACC) and NcoI (CHH context: CCATGG). Results are displayed relative to the mean value for input DNA (set to 1). Column height represents mean values; error bars represent standart deviation. C) Cytosine methylation determined by sodium bisulfite sequencing. Cumulative methylation levels at all cytosines (gray), CG (black), CHG (blue) and CHH (red). H equals C, A or T. For better compareability, mutants were group according their complementation groups determined in later experiments. Exact numbers of analyzed clones and cytosine sites are indicated in Table S7. Asterisks indicate confidence levels (χ^2 -test) for being different from *K/K;H/H* values: * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$;

It was expected that kanamycin resistance that is based on the release of TGS of the *ProNOS-NPTII* reporter is accompanied by an increase of *NPTII* transcription and thus increased *NPTII* protein levels. Only mutant lines matching this criterion were considered as “true positive” *nrd* mutants. However, only 10 out of 19 mutant lines which displayed at least 95% Kan^R plants in M₃ progeny possessed elevated *NPTII* protein levels. The

release of silencing observed in lines 1-23, 2-5, 2-11, 8-6, 9-20, 11-12, 13-14, 20-12, 26-5 and 29-8 was accompanied by reduced DNA methylation in the CHH context at the *TARGET-ProNOS*, indicative for a functioning of the affected genes in the process of RdDM rather than in processes downstream of the establishment of DNA methylation. Furthermore, the reliability of the used two-step strategy, validation of Kan^R resistance in M₃ and analysis of NPTII protein levels by ELISA, to exclude “false positive” mutants was proven. Notably, no obvious consistent developmental phenotype was observed in M₃ plants of the respective candidates (data not shown).

3.3 DNA METHYLATION OF ENDOGENOUS SEQUENCES

For lines considered to be true RdDM / RdTGS mutants, the DNA methylation status of endogenous target sequences of RdDM was determined by bisulfite sequencing and / or methylation sensitive restriction of genomic DNA and subsequent semi-quantitative PCR in genomic DNA extracted from rosette leaves of mature plants.

In particular, the sequence of the well characterized RdDM target *AtSN1*, a SINE element localized at chromosome 3 and the *INTERGENIC SUBTELOMERIC REPEAT (ISR)* of the *MEA* locus (*MEA-ISR*) were analyzed by bisulfite sequencing for all candidates (Myouga *et al.*, 2001; Cao and Jacobsen, 2002; Zilberman *et al.*, 2003). In addition, *AtMU1*, a functional transposable element, was analyzed in most candidate lines in this way (Singer *et al.*, 2001; Lippman *et al.*, 2003). Furthermore, DNA methylation of the less well characterized loci *IGN5*, *IGN23* and *IGN25* (Wierzbicki *et al.*, 2008; Wierzbicki *et al.*, 2009; Bies-Etheve *et al.*, 2009) as well as of the rolling circle transposon derived *BASHO210*, was analyzed in several candidate lines (Hollister and Gout, 2007).

AtSN1

The analyzed sequence of the SINE *AtSN1* is located between the protein coding loci *At3g44000* and *At3g44005* and corresponds to nucleotides 15,794,606 to 15,794,819 of chromosome 3. It contains 4, 7 and 35 cytosines in CG, CHG and CHH context, respectively. Bisulfite sequencing analysis of this sequence showed that approximately 68%, 64% and 29% of cytosines in CG, CHG and CHH context, respectively are methylated in leaf tissue of non-mutagenized *K/K;H/H* plants (Figure 6A). M₃ plants of all true *nrd* lines displayed a severe, significant (χ^2 -test < 0.01) decrease of overall DNA methylation. As for the *TARGET-ProNOS*, the most prominent decrease was observed for DNA methylation in the CHH context (Figure 6A). This is consistent with mutated loci

being essential for maintenance of DNA methylation in the CHH context, not only of transgenic, but also endogenous RdDM targets. In agreement with the bisulfite data obtained for the *TARGET-ProNOS*, methylation at *AtSN1* in the candidate lines 19-7 and 30-2 was found to be only slightly affected in the CHH context (data not shown). This further supported the assumption that these lines were “false positive” in respect to being affected in RdDM. However, although maintained by mechanistically distinct pathways, also some DNA methylation in CG and CHG context at *AtSN1* was impaired in lines 2-11, 11-12, 20-12, 9-20 and 13-14 as well (Figure 6A).

MEA-ISR

The direct repeats of *MEA-ISR*, a 183 bp sequence located in the intergenic region between the gene loci *At1g02580* and *At1g02590*, were found to be highly methylated in all sequence contexts in vegetative tissue of wild type plants (Cao and Jacobsen, 2002). DNA methylation of the bottom strand of *MEA-ISR*, corresponding to positions 68067 to 68320 of BAC clone T14P4, was assayed (Cao and Jacobsen, 2002). This region contains 9, 2 and 24 cytosines in CG, CHG and CHH context, respectively. Of these, 74%, 23% and 20%, respectively, were found to be methylated in *K/K;H/H* plants (Figure 6B).

Similar to *AtSN1*, methylation in CHH context was significantly reduced (χ^2 -test, $p < 0.05$) or, in case of line 2-11, completely erased at *MEA-ISR* in all analyzed mutants. Moreover, methylation in the CHG context was also found significantly (χ^2 -test, $p < 0.05$) reduced or, as in case of lines 2-11, 8-6, 13-14, 26-5 and 29-8, completely erased in the analyzed mutant lines. In contrast to *AtSN1*, methylation in the CG context was not found significantly reduced (χ^2 -test, $p > 0.05$) in any of the mutant lines, indicating that the CG context methylation maintenance independent of RdDM is more pronounced at *MEA-ISR* (Figure 6B).

AtMU1

AtMU1, an autonomous Mutator-like DNA transposon present in two copies in the genome of *A. thaliana* accession Col-0, is transcriptionally silenced in *A. thaliana* wild type plants (Le *et al.*, 2000; Singer *et al.*, 2001). In mutants impaired in DNA methylation, such as *ddm1*, *met1*, *hda6* and *cmt3*, a decreased DNA methylation at the terminal inverted repeats (TIRs) of *AtMU1* was observed. This is accompanied by the reactivation of *AtMU1* transcription and transposition, thus linking silencing of this transposon with DNA methylation (Singer *et al.*, 2001; Lippmann *et al.*, 2003). The same study implied

that silencing of *AtMU1* depends on the existence of siRNAs that direct DNA methylation to its TIRs. Further studies clearly depict *AtMU1* as target of the RdDM machinery (Bäurle *et al.*, 2007; Bäurle and Dean, 2008; He *et al.*, 2009).

A possible impairment of the DNA methylation of a 420 bp sequence defined by primers JP1387 and JP1388 at the *AtMU1* copy located at chromosome 4 (*At4g08680*) was analyzed in lines 1-23; 2-5; 2-11; 8-6; 26-5 and 29-8. This sequence covers the TIR which is of about 300 bp in length. Per clone 80 cytosine residues were assayed, of which 6 each are in CG and CHG context and 68 are in CHH context.

AtMU1 sequences in wild type *K/K;H/H* were found to display 79%, 48% and 24% DNA methylation in CG, CHG and CHH context, respectively. Methylation in the CHH context was found to be significantly reduced (χ^2 -test, $p < 0,001$) in all mutant lines analyzed. However, in contrast to the previously analyzed *AtSN1* and *MEA-ISR* sequences, considerable amounts of CHH methylation remained at *AtMU1*, most likely maintained by the partially redundant mechanisms involving *CMT3*. Methylation levels in CG and CHG context were only mildly affected in most lines. Only lines 8-6, 26-5 and 2-11 displayed significant (χ^2 -test, $p < 0,05$) lower DNA methylation in CHG context (Figure 6C).

AtCOPIA4

To address the question whether the obtained mutations also affected DNA methylation that is not dependent on the RdDM mechanism, DNA methylation of the Ty1/copia-like retrotransposon *AtCOPIA4/COPIA-LIKE23* (*AtCOPIA4*) was determined by bisulfite sequencing. DNA methylation at *AtCOPIA4* is mainly found in the CG context and is reduced in *ddm1* and *met1* mutants (Johnson *et al.*, 2007; Lippman *et al.*, 2003).

The analyzed sequence region corresponding to the nucleotides 9,485,799 to 9,486,321 of chromosome 4 contained in total 175 cytosines, 25 in CG, 22 in CHG and 128 in CHH context (Figure S2). Approximately 92%, 52% and 9% of cytosines in CG, CHG and CHH context, respectively, were found to be methylated in *K/K;H/H* wild type individuals. None of the mutants analyzed displayed significant (χ^2 -test, $p < 0.05$) alterations in DNA methylation in any sequence context compared to wild type *K/K;H/H* plants (Figure 6D).

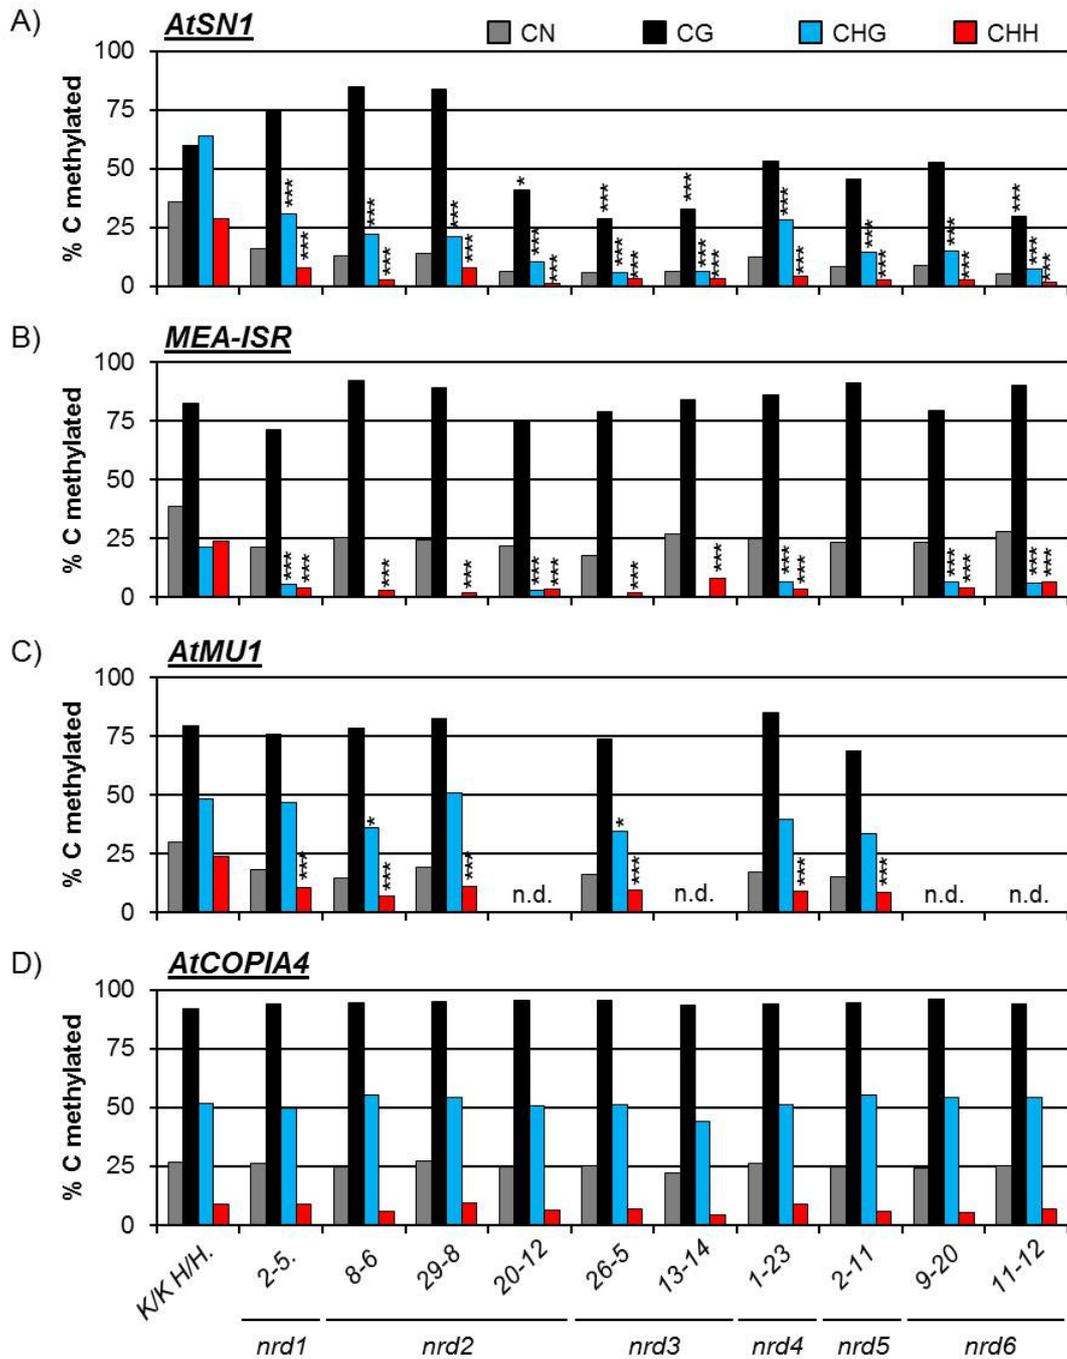

Figure 6: DNA methylation at well characterized endogenous sequences.

DNA methylation patterns of endogenous sequences (A) *AtSN1*, (B) *MEA-ISR*, (C) *AtMU1* and (D) *AtCOPIA4* were analyzed in detail by bisulfite sequencing in non-mutagenized control plants (*K/K;H/H*) and isolated mutants. Percentage of cytosine methylation independent of the context (grey columns), in the CG context (black columns), CHG context (blue columns) and CHH context (red columns) are displayed. For better comparability, lines later known to contain allelic mutations are displayed next to each other. Respective putative *nrd* complementation groups are depicted below diagrams. Degrees of significance are indicated. Asterisks indicate confidence levels (χ^2 -test) for being different from *K/K;H/H* values: * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$; Exact numbers of analyzed clones and cytosine sites are indicated in Table S7. n.d. = not determined.

Intergenic non-coding loci

Studies by Wierzbicki *et al.*, (2008) lead to the identification of transcripts from intergenic non-coding regions (*IGN*) in the heterochromatic knob of chromosome 4 (Fransz *et al.*, 2000) that are synthesized by Pol V. AGO4 as well as SPT5L are recruited to chromatin by physical interaction with these transcripts and mediate methylation of the corresponding DNA sequences (Wierzbicki *et al.*, 2009; Bies-Etheve *et al.*, 2009; Rowley *et al.*, 2011). In consequence, DNA methylation at *IGN* sequences is reduced in mutants such as *nrpd2a/nrpe2a*, *nrpe1*, *drd1*, *dms3* and *rdm1* which are impaired in *IGN* transcription.

DNA methylation level in the CHH context at *IGN5*, *IGN23* and *IGN25* was investigated by methylation-sensitive restriction cleavage using HaeIII followed by semi-quantitative PCR in mutant lines *1-23*, *2-5*, *2-11*, *8-6*, *9-20* and *26-5*. Furthermore, bisulfite sequencing of *IGN5* and *IGN23* was performed for selected mutant lines (Figure 7A and Figure 7B). At all three loci, DNA methylation was reduced in M₃ plants of mutants *8-6*, *26-5*, *2-11* and *9-20*. In contrast, methylation of *IGN5* and *IGN23* persisted in *2-5* and methylation at *IGN5-A* and *IGN25* in *1-23*. To confirm previous results, bisulfite sequencing of the analyzed fragments of *IGN5* and *IGN23* was carried out in M₃ individuals of *8-6* and *1-23*.

The analyzed sequence of the top strand of *IGN5* is 210 bp in length and corresponds to nucleotides 2,323,140 to 2,323,350 of chromosome 4 (Wierzbicki *et al.*, 2008). It contains 3, 4 and 33 cytosines in CG, CHG and CHH context, respectively, of which 87%, 79% and 32%, respectively, were found methylated in *K/K;H/H* wild type individuals (Figure 7B and Figure S1). In line *1-23*, approximately 85%, 75% and 26% of CG, CHG and CHH context cytosines were found to be methylated, respectively, and no significant reduction in either of the contexts was observed (χ^2 -test, $p > 0.05$). In contrast to this result, methylation in all sequence contexts was significantly reduced in line *8-6* (χ^2 -test, $p < 0.001$).

The analyzed sequence of *IGN23* is 179 bp in length and corresponds to the coordinates 2,577,896 to 2,578,075 at chromosome 4. It contains 11 CG, 10 CHG and 27 CHH context cytosines, respectively (Figure S1). In wild type individuals, 64%, 38% and 17% of cytosines in the respective contexts were found to be methylated. In contrast, methylation in the CHG context is significantly reduced and in the CHH context almost completely erased in the analyzed mutant lines, whereas the CG methylation is significantly increased in the mutants (χ^2 -test, $p < 0.001$) (Figure 7B).

Results

Taken together, the bisulfite sequencing data rather well confirmed the results obtained for these lines by restriction cleavage and PCR.

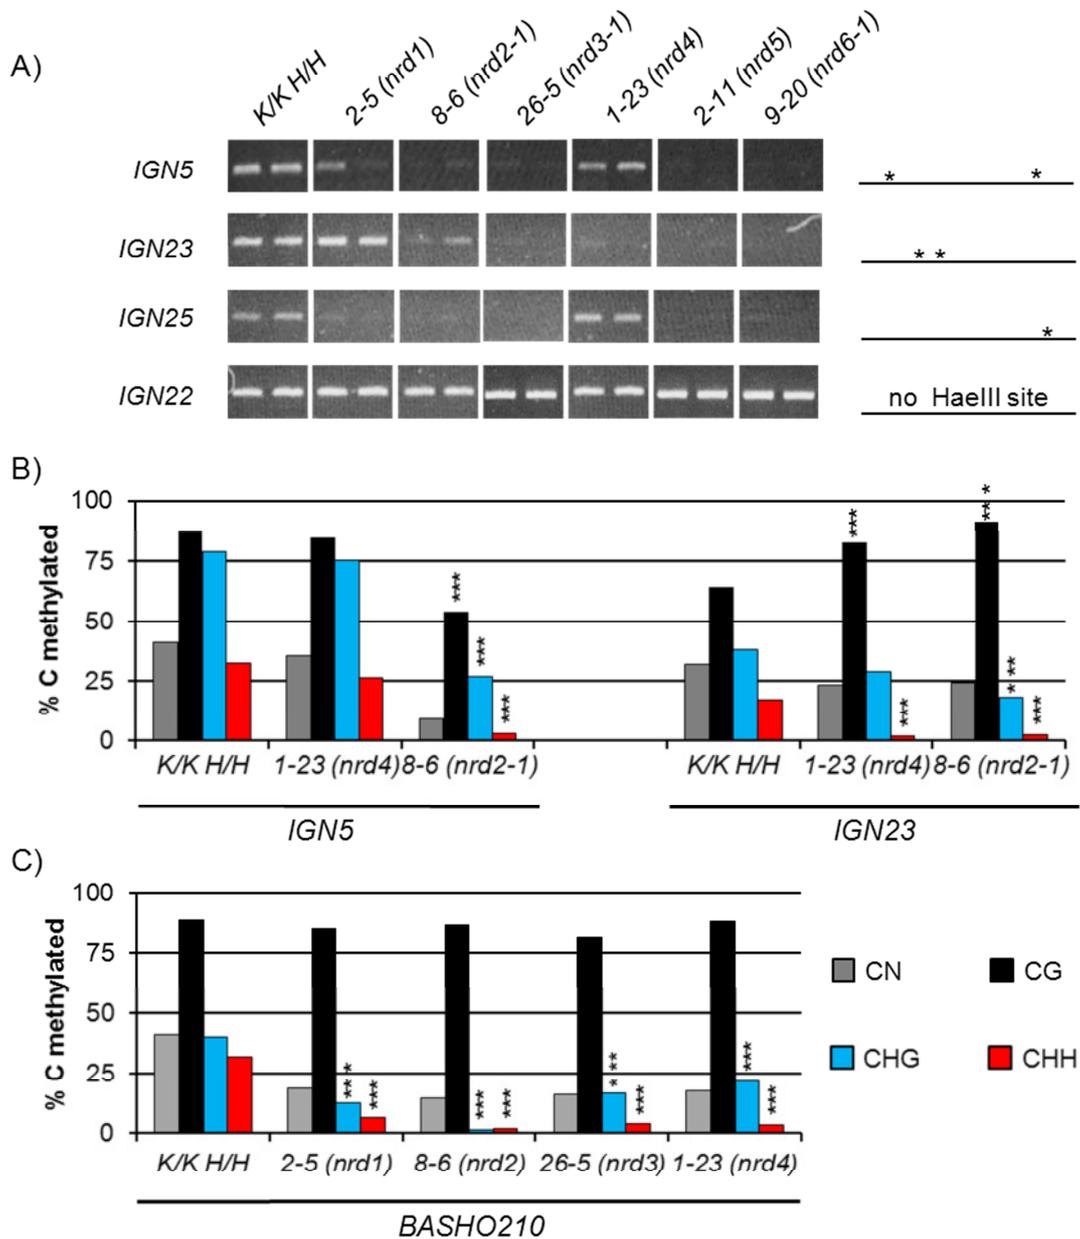

Figure 7: DNA methylation at *IG N* loci and *BASHO210*.

A) Methylation-sensitive restriction cleavage using HaeIII followed by semi-quantitative PCR. DNA preparations from two individual plants per genotype were assayed. The positions of HaeIII restriction sites in *IG N* sequences are marked by asterisks. *IG N22*, which does not contain HaeIII recognition sites, served as loading control. B) Bisulfite sequencing of *IG N5-A* and *IG N23* in M_3 individuals of *8-6* and *1-23*. C) Bisulfite sequencing of *BASHO210* in M_3 individuals of *K/K;H/H*, *2-5*, *8-6*, *26-5* and *1-23*. Degrees of significance are indicated. Asterisks indicate confidence levels (χ^2 -test) for being different from *K/K;H/H* values: *** $p < 0.001$; Numbers of clones and sites analyzed are provided in Table S7.

BASHO210

Helitrons are a recently described class of eukaryotic DNA transposons which are found in high copy numbers in the genomes of *A. thaliana* and *Oryza sativa* (*O. sativa*) as well as the nematode *Caenorhabditis elegans* (*C. elegans*), and other members of other eukaryote kingdoms (Kapitonov and Jurka, 2007; Cocca *et al.*, 2011). In *A. thaliana*, helitrons and helitron-derived elements represent more than 2% of the genome sequence (Kapitonov and Jurka, 2001). It is assumed that the propagation of helitron elements is conferred by a rolling circle mechanism (Kapitonov and Jurka, 2001). Features of all identified autonomous and non-autonomous helitrons are a TA dinucleotide and a CTRR (R stands for A or G) sequence in their 5' and 3' termini, respectively, the presence of hairpin structures close to their 3' termini and the absence of TIRs. A further hallmark of helitrons is their capability to capture host gene fragments and to transpose these to other locations, potentially causing new protein activities by exon shuffling (Bennetzen *et al.*, 2005; Morgante *et al.*, 2005, Lai *et al.*, 2005).

The *BASHO*-family is a subfamily of non-autonomous helitrons recently described in *A. thaliana* (Hollister and Gaut, 2007). *BASHO210* is a member of subclade V of this family. It is part of the gene coding locus *At2g27070*. In particular, it contributes the 10th exon of the gene. DNA methylation at the 5' end of *BASHO210*, was analyzed in lines 2-5, 8-6, 26-5 and 1-23 as well as in wild type. The analyzed sequence defined by primer *BS-5-B210-F* and *BS-5-B210-R* corresponds to nucleotides 11,555,814 to 11,556,371 of chromosome 2, has a length of 558 bp and contains 9, 4, and 46 cytosines in the CG, CHG and CHH context, respectively (Figure S1). Bisulfite sequencing revealed that 89%, 40% and 32% of cytosines in the CG, CHG and CHH context, respectively are methylated in *K/K;H/H* wild type plants. While the CG context methylation was not affected, the CHH methylation was almost completely erased in all analyzed mutants. Furthermore, methylation in the CHG context was found significantly reduced in all analyzed mutant lines. Noteworthy, methylation in this context was found to be almost absent in line 8-6 (Figure 7C).

3.4 PRONOS DERIVED SIRNAS

In general, the RdDM pathway can be divided in two major steps: First, the generation of the target specific silencing signal (i.e. the production of the 24 nt siRNAs) and, as the second step, the interpretation of this signal and the establishment of the DNA methylation at the target sequence. To determine if the former or the latter step is

affected in the isolated mutant lines, Northern blot analysis addressing the amounts of 24 nt *ProNOS* siRNAs derived from the *ProNOS-IR* of the *H transgene* was conducted in RNA preparations enriched for “small” RNAs from individual plants of lines 2-5, 2-11, 8-6, 9-20, 11-12, 13-14, 26-5 and 29-8 grown at short day conditions for 8 weeks. In agreement with the absence of DNA methylation at the *TARGET ProNOS*, no *IR*-derived siRNAs were detected in *K/K;-/-* individuals, whereas noticeable amounts were detected in plants containing both transgenes. Moreover, 24 nt *ProNOS-IR*-derived siRNAs were not markedly reduced in any of the analyzed mutant lines if compared to *K/K;H/H* plants, indicating that the mutated factors are not involved in the synthesis or the stabilization of these siRNAs, but rather affects their perception and interpretation (Figure 8).

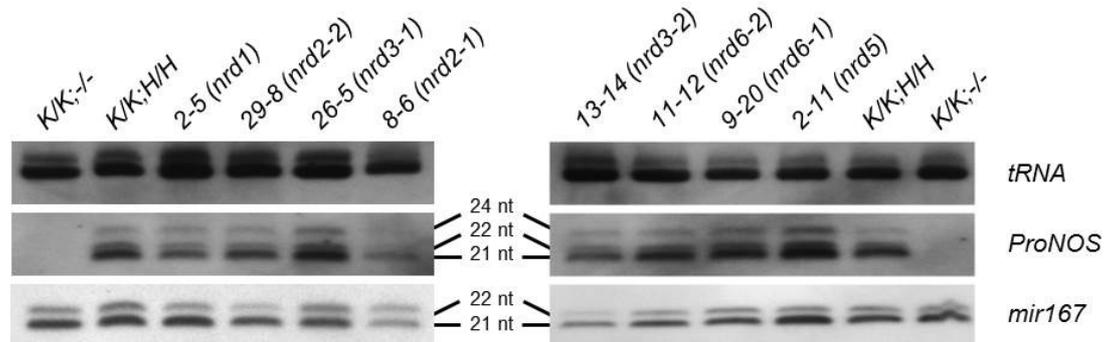

Figure 8: *ProNOS*-derived siRNAs in mutant lines.

Northern blots for siRNA derived from transcripts of the *ProNOS-IR* in the *H transgene*. Blots were hybridized with a RNA probe specific for sense *ProNOS* siRNAs (middle panels). Loading was checked by unspecific hybridization signals of tRNA with the RNA probe (top panels) as well as by re-hybridization with an end-labeled *mir167*-specific probe after stripping (lower panels).

3.5 IDENTIFICATION OF NRD MUTATIONS

Mutations causative for the impairment of RdTGS and accompanying RdDM were identified by a combination of map-based cloning and DNA sequencing techniques, resulting in so far six complementation groups termed *nrd1* to *nrd6*.

3.5.1 IDENTIFICATION METHODS

Map-based cloning

Map-based cloning uses the genetic linkage of a mutation causing a scorable phenotype to sequence polymorphisms at known positions in the genetic or physical map. To determine the position of a mutation, crosses between a mutant in a certain accession and a genetically distinguishable accession are performed. During gametogenesis in the F_1 progeny, stochastically positioned recombination events between homologous chromosomes derived from the parental accessions in meiosis generate “chimeric”

chromosomes. If F_1 plants are then allowed to set seeds by self-pollination, a recessive mutant phenotype will only show up in resulting F_2 individuals that are homozygous for the relevant mutation and, in consequence, contain two copies of the chromosome region surrounding the causative gene locus derived from the one accession that was submitted to mutagenesis. Thus, the position of a mutation can be localized by testing populations of phenotypically mutant F_2 individuals for the positions of recombination events, using e.g. co-dominant markers based on insertion / deletion (InDel-markers) or single nucleotide polymorphisms [Cleaved amplified polymorphisms (CAPS)-markers]. The area containing the relevant mutant gene locus is thus defined by 100% incidence of homozygosity for the marker alleles derived from the respective accession in which the mutation was established; in consequence, the region in which a mutation resides is defined by the closest recombination events known to each flanking side. In this thesis, InDel, CAPS as well as Illumina GoldenGate SNP makers were employed to localize the mutations. Prior to the mapping of mutations, the related genotyping methods were tested in a control F_2 population (C_3F_2) obtained by selfing of F_1 progeny of a cross between $K/K;H/H$ wild type plants (accession Col-0) and non-transgenic Ler. As done later by the selection for $Kan^R Hyg^R M_3F_2$ individuals in the mapping of mutations, the presence of K and H transgenes in at least the heterozygous state in the C_3F_2 progeny was ensured by first selecting for Hyg^R individuals (presence of H) and then for plants positive for β -glucuronidase activity (GUS^+ , presence of K). The GUS^+ criterion was used as the *Pro35S-GUS* reporter gene in K is in contrast to the *ProNOS-NPTII* reporter not sensitive to the silencing effect of the *ProNOS-IR*.

Of 220 C_3F_2 individuals screened on GM containing 20 mg/l hygromycin, 152 (69%) displayed a Hyg^R phenotype. Ninety-four of these were further screened for GUS activity, finally resulting in 66 (70%) $Hyg^R GUS^+$ C_3F_2 plants. According to Mendelian segregation, a distribution of 25% homozygosity for the Col-0 allele, 50% heterozygosity and 25% homozygosity for the Ler allele was expected in this population for all analyzed marker loci that were not genetically linked to K or H transgenes, while higher incidences of Col-0 alleles were expected for marker loci that were genetically linked to the transgenes.

Genotyping of the $Hyg^R GUS^+$ C_3F_2 population was performed using 20 co-dominant InDel markers. A significant (χ^2 -test, $p < 0,05$) bias against homozygosity for Ler alleles for markers *CER461145* and *CER452833* close to the insertion sites of the K and H transgenes on the lower arms of chromosomes 1 and 4, respectively, was observed (Figure 9). In addition, significant shifts (χ^2 -test, $p < 0,05$) towards higher incidence of Col-

Results

0 alleles was observed for markers located on chromosome 5 (*CER482932*, *CER450021*, *CER454594*) and lower incidence of Col-0 alleles for markers located on chromosome 2 (*CER460670*, *CER466780*, *CER448739*).

To accelerate genotyping and to increase the marker density, an Illumina GoldenGate assay (GoldenGate assay) allowing multiplex genotyping was developed. As with InDel markers, genotyping of the Hyg^R GUS⁺ C₃F₂ population with the GoldenGate assay revealed a significant bias against homozygosity for *Ler* alleles for markers physically close to the insertion sites of both transgenes at the lower arms of chromosome 1 and 4, respectively. In agreement with the InDel markers, a significant shift towards low incidences of Col-0 alleles was observed for markers located on chromosome 2 (*ILM2-1*, *ILM2-2*, *ILM2-3*, *ILM2-4*). In addition, a shift towards high incidences of Col-0 alleles was also observed for chromosome 5.

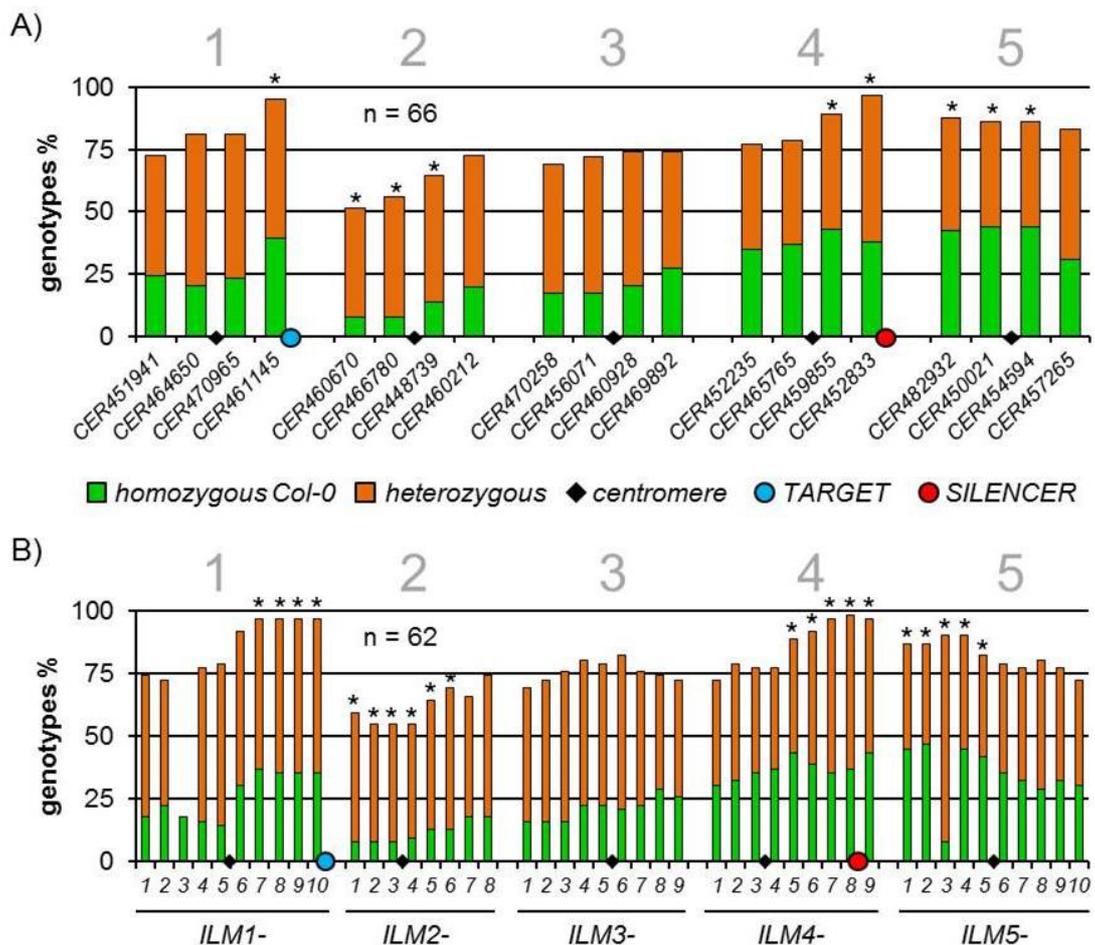

Figure 9: Marker allele incidences in a Hyg^R GUS⁺ C₃F₂ population.

Marker allele incidences for A) the initial InDel marker set and B) for Illumina GoldenGate markers. Marker loci showing significant distortion of Mendelian segregation (χ^2 -test, $p < 0.05$) for any of the three possible genotypes are marked by asterisks. Grey numbers above diagrams refer to chromosomes, marker located on upper / lower arm of respective chromosome are displayed left / right of the centromere indicated by a black diamond. Positions of transgenes are indicated by blue (*K*) and red (*H*) circles.

Interestingly, tests with markers *ILM5-2* and *ILM5-4* scored approx. 50% of plants homozygous for the Col-0 allele, while tests for marker *ILM5-3* located between these markers displayed a very low percentage of plants homozygous for the Col-0 allele (Figure 9B). To verify this result, CAPS marker *C5-3443965* (*At5g10920*), *C5-5609978* (*At5g17050*) and *C5-7193938* (*At5g21150*), physically close to *ILM5-2*, *ILM5-3* and *ILM5-4*, respectively, were tested and confirmed the results obtained by the GoldenGate assay (Table S6). Thus, there seem to be a region with apparently distorted recombination in this area. Additional CAPS markers located between *ILM5-2* and *ILM5-4* were tested to estimate the size of the distortion. A comparably high number of recombination events between markers *C5-4165329* (*At5g13120*) and *C5P0888834* (*At5g14020*) and between markers *C5-5609978* (*At5g17050*) and *C5-6086383* (*At5g18370*), respectively suggested a chromosome area of approximately 1.9 Mb to be affected. This recombination distortion had to be taken into account while determine the positions of the mutations.

Whole genome sequencing

Due to the recent availability of cost effective next generation sequencing technologies, whole genome sequencing (referred to as NGS) of a number of M_3 mutant plants was performed to identify mutations present in their genomic DNA.

As the introduction of the *K* and *H* transgenes into Col-0 plants *via A. tumefaciens* mediated transformation could have had a mutagenic effect by itself, the genome of the used *K/K;H/H A. thaliana* wild type line might already have contained sequence deviations from the published Col-0 reference sequence (The Arabidopsis Genome initiative, 2000) prior to submission to EMS mutagenesis. However, due to the stable silencing of the NPTII gene in *K/K;H/H* wild type plants, these possible sequence deviations could not be causative for the release of RdTGS and thus had to be excluded in the interpretation of sequence data.

NGS of DNA from a non-mutagenized *K/K;H/H* plant yielded 62,130,438 unique reads, of which approximately 96% (59,828,453 reads) were successfully mapped to the *A. thaliana* nuclear or organelle genome sequences. 54,342,788 of these reads corresponded to sequences of the five *A. thaliana* chromosomes, whereas the remaining ones corresponded to mitochondrial and chloroplast DNA. Comparison to the *A. thaliana* reference sequence (TAIR 10) for the nuclear genome identified 2886 variant positions, of which 309 cause non-synonymous mutations in coding sequences (CDS) of annotated *A. thaliana* genes (data not shown).

3.5.2 *NRD1* IS ALLELIC TO *INVOLVED IN DE NOVO 2*

Map based cloning and sequence analysis of *nrd1*

Screening of 305 M₃F₂ plants derived from a cross of mutant M₃ 2-5 with Ler for Kan^RHyg^R individuals resulted in the identification of 32 resistant plants. This incidence of approximately 10% resistance plants fits quite well with the 14% expected for a single-locus recessive mutation. Genotyping of the initial mapping population using InDel markers showed a high incidence of homozygosity for the Col-0 allele for marker *CER460928* localized on the lower arm of chromosome 3 (Figure 10A). To exclude occasional “false positive” plants, M₃F₃ progeny obtained by self-pollination of M₃F₂ individuals that were either heterozygous or homozygous for the Ler allele of the highest scoring marker were tested for the segregation of the Kan^R Hyg^R phenotype. Lines which display markedly less than the expected 56% of Kan^R Hyg^R M₃F₃ were removed from the analysis. Using an extended mapping population of 117 Kan^R Hyg^R M₃F₂ individuals, the localization of the related *nrd1* mutation on the lower arm of chromosome 3 was further

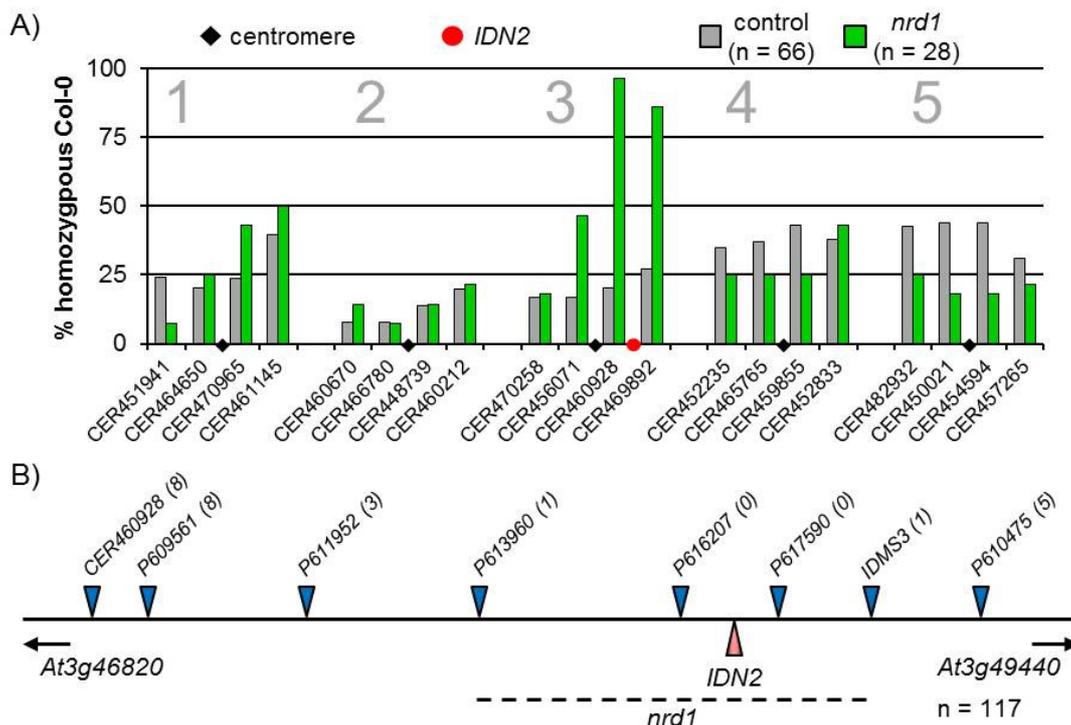

Figure 10: Mapping of *nrd1*

A) Marker allele incidences for the initially tested InDel markers in *nrd1* Kan^R Hyg^R M₃F₂ compared to a Hyg^R GUS⁺ C₃F₂ population. Displayed values are based on an initial mapping population after exclusion of “false positive” plants. Markers located left/right of the centromere are located at the upper/lower arm. The position of *IDN2* is indicated by a red dot. B) Physical map indicating markers and recombination events (numbers in parenthesis) used to delineate position of *nrd1* on the lower arm of chromosome 3. Data are based on a mapping population of 117 plants after removal of “false positive” plants.

mapped to an area defined by recombination events between markers *P613960* and *P616207* as well as *P617590* and *IDMS3*, respectively. These recombination events define an area of approximately 555kb physical distance between *At3g46820* and *At3g49440* (Figure 10B). Sequencing of the gene *At3g48670* which is localized within this region and is coding the previously described RdDM factor *IDN2* revealed a G → A mutation in exon 5 of the gene at position 1883 (Figure 11A). The identified mutation causes the exchange of glycine 514 (G514) for an arginine (R) at protein level (Figure 11B). Protein sequence alignments of *IDN2* and its related proteins in *A. thaliana* reveals the evolutionary conservation of G514 (Figure 11C) (Zhang *et al.*, 2012, Xie *et al.*, 2012a, Finke *et al.*, 2012b). Semi-quantitative RT-PCR did not show any notable reduction of *idn2* transcript in *nrd1* compared to *K/K;H/H* wild type plants (Figure 11D). Hence, it can be concluded that G514 is of functional importance and its mutation give rise to a non-functional protein.

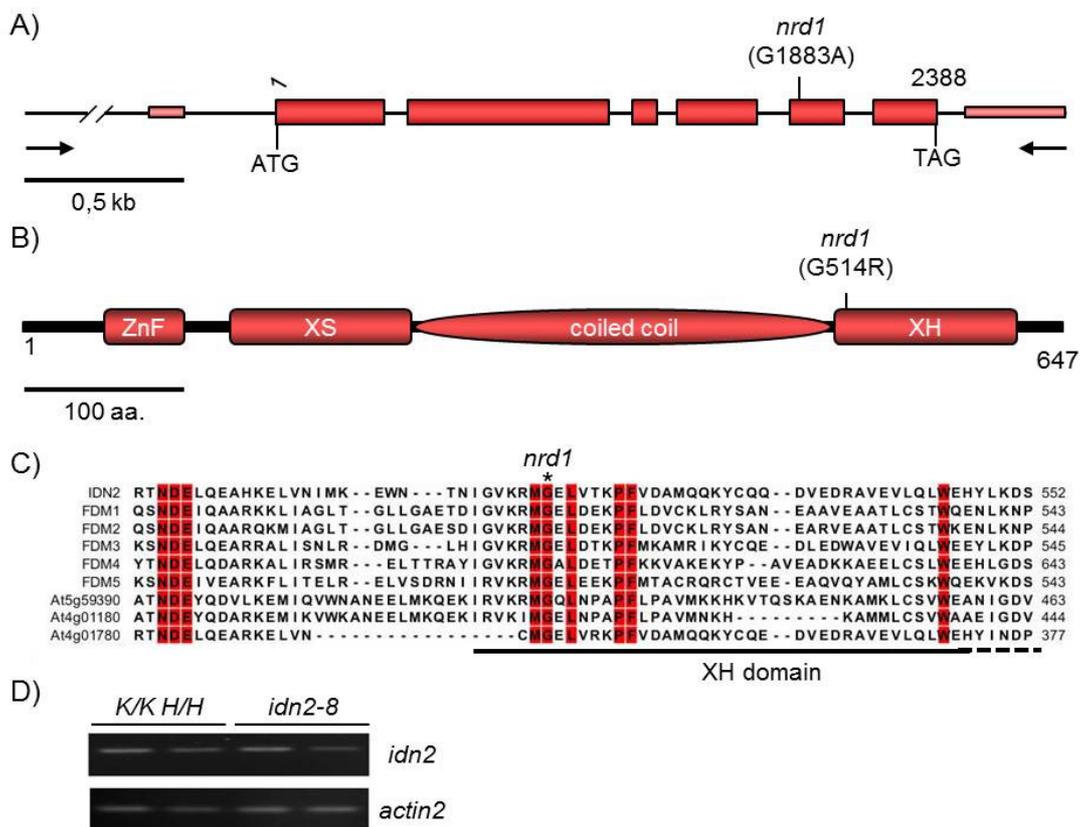

Figure 11: The nature of the mutation in *nrd1*

.A) Gene model of *IDN2* (*At3g48670*) indicating the mutation in *nrd1* at position 1883. Numbering is according to the genomic sequence relative to the first nucleotide of the START codon. Arrows indicate the location of the primers used to amplify the wild type gene. B) Protein model of *IDN2* indicating the position of the G514R amino acid exchange. The approximate sizes and positions of protein domains are according to the Pfam database (Punta *et al.*, 2012). C) Protein sequence alignment of the XH domain of *IDN2* and related proteins in *A. thaliana*. The G residue mutated in *nrd1* is indicated by an asterisk. Sequence alignment was performed using full length protein sequences and ClustalW2 (Larkin *et al.*, 2007) D) Semi-quantitative RT-PCR of *IDN2* and *nrd1/idn2* mRNA. *actin2* was used as reference gene.

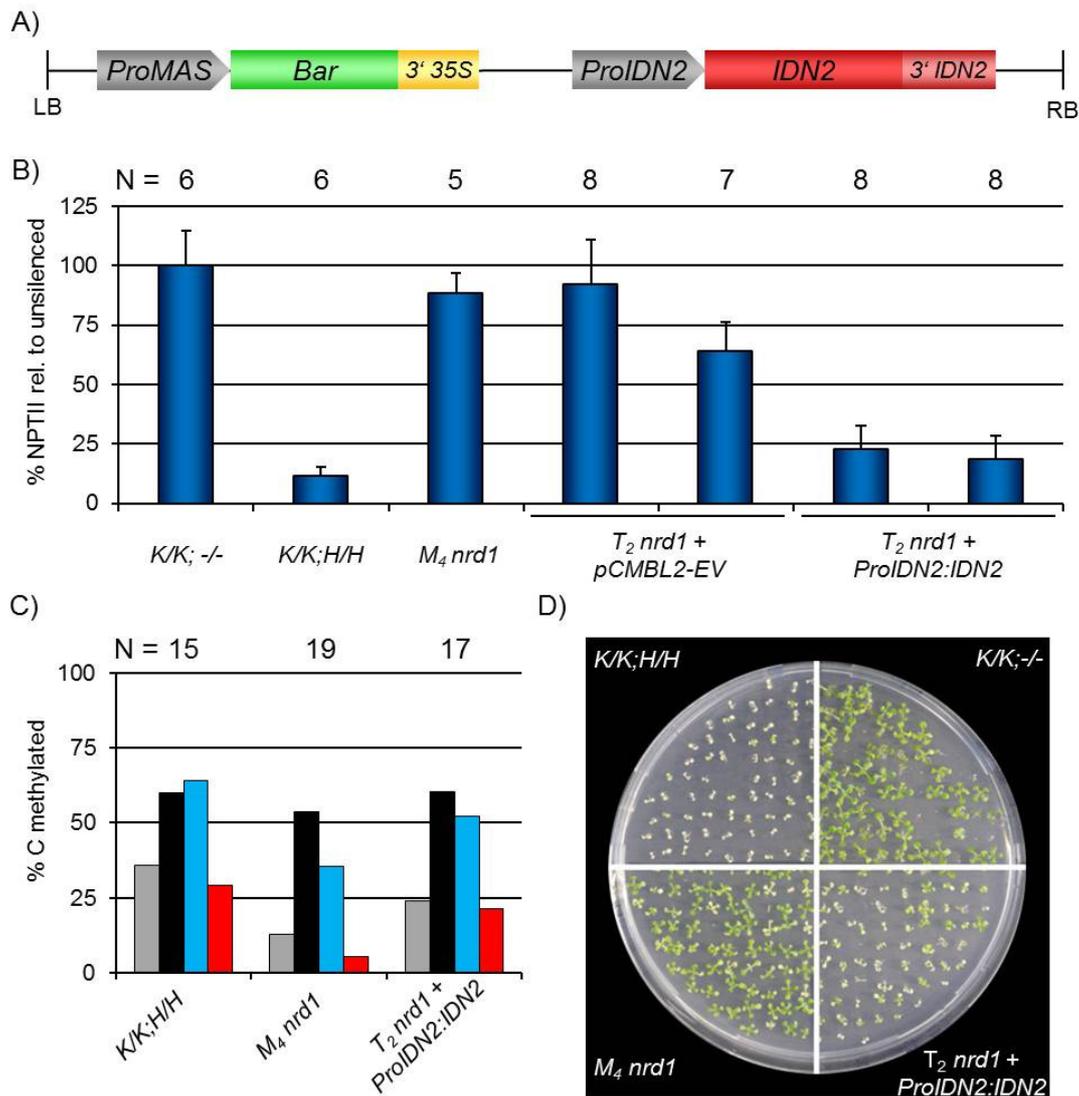

Figure 12: Complementation of *nrd1* by *ProIDN2:IDN2*.

A) T-DNA construct used for complementation of *nrd1* B) NPTII ELISA of *T₂* progeny of two independent primary transformants and controls (*T₂* progeny of empty vector transformants, *K/K; -/-*, *K/K; H/H*, *M₄ nrd1*). Column heights represent mean values, error bars represent standard deviation. The number of plants assayed per genotyped is depicted above the diagram C) DNA methylation in CHH context (red columns) at *AtSN1* is reestablished in *T₂* individuals after introduction of *ProIDN2:IDN2*. Numbers of clones analyzed are depicted above the diagram C) Segregation of *Kan^S* phenotype in *T₂* progeny after introduction of *ProIDN2:IDN2*. Approximately 75% of assayed individuals displayed the *Kan^S* phenotype indicating the successful complementation of *nrd1*.

Complementation of *nrd1*

To verify that the isolated *idn2* allele is causative for the release of RdTGS in *nrd1*, the coding region of *IDN2* under the control of its native promoter (*ProIDN2:IDN2*) was amplified from genomic DNA of wild type Col-0 via PCR and introduced into *nrd1* *M₃* plants by *A. tumefaciens* mediated transformation. In parallel transformation of *nrd1* *M₃* plants with the empty binary vector *pCMBL2* (*pCMBL2-EV*) was carried out as a control. The screening of approx. 3×10^5 seedlings germinated from seeds obtained after floral

dip transformation for BASTA resistant (BASTA^R) individuals resulted in 26 primary (T₁) transformants.

T₂ progeny obtained by self-pollination of five independent T₁ individuals was tested for Kan^R on GM containing 200 mg/l kanamycin. In addition, the segregation of the BASTA^R phenotype was assayed in the T₂ progeny. In four out of five lines tested, approximately 75% of the T₂ progeny showed sensitivity towards kanamycin (Figure 12C). The same held true for the incidence of BASTA^R T₂ plants. Furthermore, the *NPTII* expression in T₂ progeny of two of the complemented lines was assayed. T₂ plants positive for the *ProIDN2:IDN2* displayed severely lower levels of NPTII protein than comparable M₄ individuals of *nrd1* and resembled *K/K;H/H* individuals (Figure 12A). Moreover, cytosine methylation at *AtSN1* was reestablished in T₂ progeny after introduction of *ProIDN2:IDN2* (Figure 12B). In summary, the complementation confirmed that *nrd1* is a new loss-of-function allele of *IDN2*. According to *idn2* alleles described previously (Ausin *et al.*, 2009; Zheng *et al.*, 2010; Xie *et al.*, 2012; Lorkovic *et al.*, 2012), *nrd1* was designated as *idn2-8* (Finke *et al.*, 2012b).

3.5.3 *NRD2* MUTATIONS ARE ALLELIC TO *NRPD2A*

Map based cloning as well as whole genome sequencing approaches revealed that candidates *8-6*, *29-8* and *20-12* are allelic mutants.

Map based cloning

The mutations in candidates *8-6* and *29-8* (*nrd2-1* and *nrd2-2*) were mapped to a region at the upper arm of chromosome 3 using a mapping population of 79 and 67 Kan^R Hyg^R M₃F₂ plants, respectively (Figure 13). The region spanned approx. 829kb physical distance and was defined by recombination events between markers *C3AB015474* and *C3P0484614* as well as between marker *MN38693286* and *CER456071*. Sequencing of *NRPD2a* (*At3g23780*), a gene locus within this region known to be involved in RdDM, revealed G → A mutations in exon 2 at position 1590 (*nrd2-2*) and exon 7 at position 5977 (*nrd2-1*) of *NRPD2a*. This locus encodes the common second-largest subunit of Pol IV and V (Herr *et al.*, 2005; Kanno *et al.*, 2005; Onodera *et al.*, 2005; Pontier *et al.*, 2005; Ream *et al.*, 2009). While the mutation in *nrd2-2* causes the exchange of a glycine for an aspartate at position 174 (G174D) of the protein, the mutation identified in *nrd2-1* leads to the exchange of a glutamate for a lysine at position 1079 (E1079K).

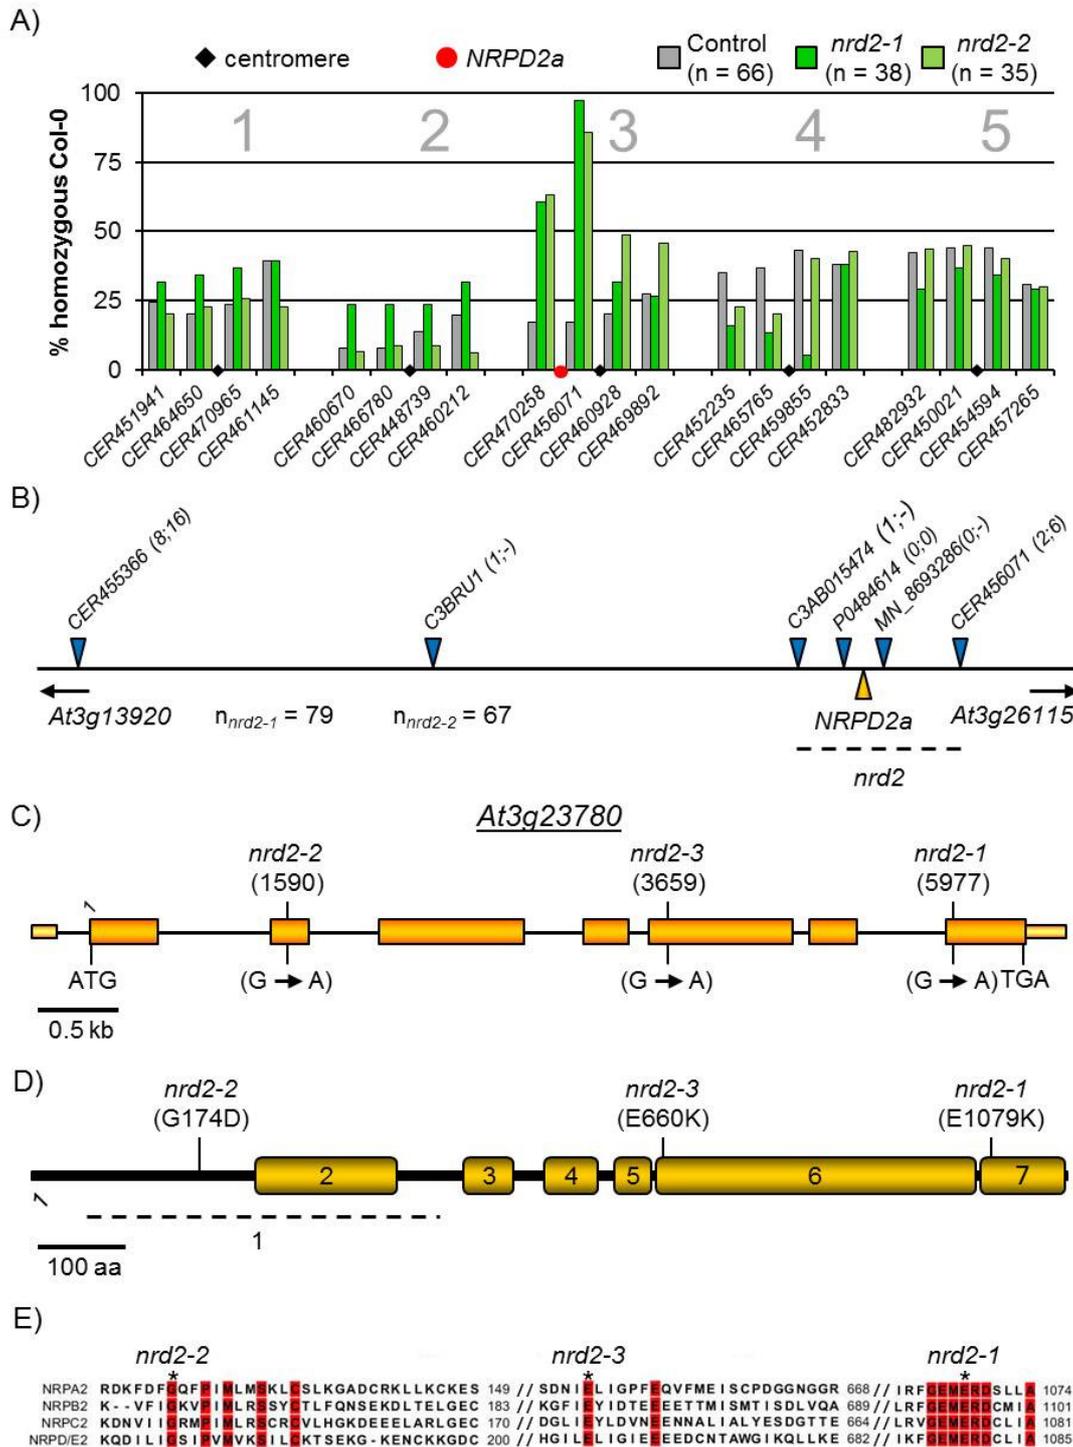

Figure 13: *nrd2*

A) Marker allele incidences among the initial set of InDel markers in Kan^R Hyg^R M₃F₂ populations derived from *nrd2-1* and *nrd2-2* after of “false positive” individuals. B) Fine mapping. Recombination events are depicted in parentheses for *nrd2-1* and *nrd2-2*, respectively. C) Gene model of *NRPD2a*. Positions and base pair exchanges for identified *nrd2* alleles are depicted above sequence. Numbering is relative to the first nucleotide of the START codon. D) Protein model of NRPD2a. Positions and nature of amino acid exchanges are displayed. Size and position of conserved protein domains are displayed according to the Pfam database (Punta *et al.*, 2012). E) Protein sequence alignment of second largest subunits of *A. thaliana* NRPs. Evolutionary conserved residues are highlighted in red. Residues affected in *nrd2* mutants are marked by asterisks. For alignment, full length protein sequences and ClustalW2 (Larkin *et al.*, 2007) were used.

Sequence alignments of NRPD2a-related second-largest subunits of DNA dependent RNA polymerases (Pol I, Pol II, Pol III) of *A. thaliana* and of other eu- and prokaryotic organisms revealed an evolutionary conservation of the affected residues in all of these proteins (Figure 13 and Figure S3). Hence, it was concluded that these amino acid residues were of functional importance and that the respective altered proteins are non-functional.

Complementation test using *nrd2-1* and *nrd2-2*

To proof that the *nrd2a* alleles identified in *nrd2-1* and *nrd2-2* cause the observed release of RdTGS and RdDM, crosses between these alleles were carried out and the amount of the NPTII protein was determined by ELISA in F₁ individuals grown under a long day regime for 5 weeks. The F₁ progeny of crosses between *nrd2-1* and *nrd2-2* display clearly more NPTII protein compared to the F₁ progeny of control crosses performed between *K/K;H/H* wild type plants and *nrd2-1* or *nrd2-2* (Figure 14A). Allelism was further supported by persistent low DNA methylation at the *AtMU1* locus in F₁ plants from the *nrd2-1* x *nrd2-2* crosses, which resembled the DNA methylation in the M₄ progeny of *nrd2-1*. Interestingly, *AtMU1* methylation in the F₁ progeny of the control crosses of *K/K;H/H* wild type plants and *nrd2-1* or *nrd2-2* seemed to be reestablished, but did not immediately revert to initial wild type levels (Figure 14B).

In addition to the analysis of the F₁ generation, segregation of the Kan^R phenotype in F₂ progeny was determined. Almost all (237 of 250; 95%) F₂ seedlings derived from non-complementing F₁ displayed Kan^R phenotypes. In contrast, only 19% (47 of 253) and 15% (35 of 241), respectively, were found to be Kan^R in F₂ progeny of the control crosses of *nrd2-1* or *nrd2-2* to *K/K;H/H* plants containing functional NRPD2a, coming rather close to the expected 25% (Figure 14C).

Thus, *nrd2-1* and *nrd2-2* were confirmed to be *nrd2a* loss-of-function mutants. According to the recent numbering they were designated as alleles *nrd2a-54* and *nrd2a-55* (Lopez *et al.*, 2011; Finke *et al.*, 2012b).

Identification of *nrd2-3* by whole genome sequencing

In *20-12* (*nrd2-3*) a mutation in the *NRPD2a* gene was detected by next generation sequencing (NGS). In total, 45,562,872 reads were obtained of which 40,715,378 reads were properly mapped to sequences in the five chromosomes of *A. thaliana*. On average every base pair was covered by 32 reads. Data analysis resulted in the identification of 1086 SNPs in the sequenced M₃ plant of *nrd2-3* that were not present in the sequenced

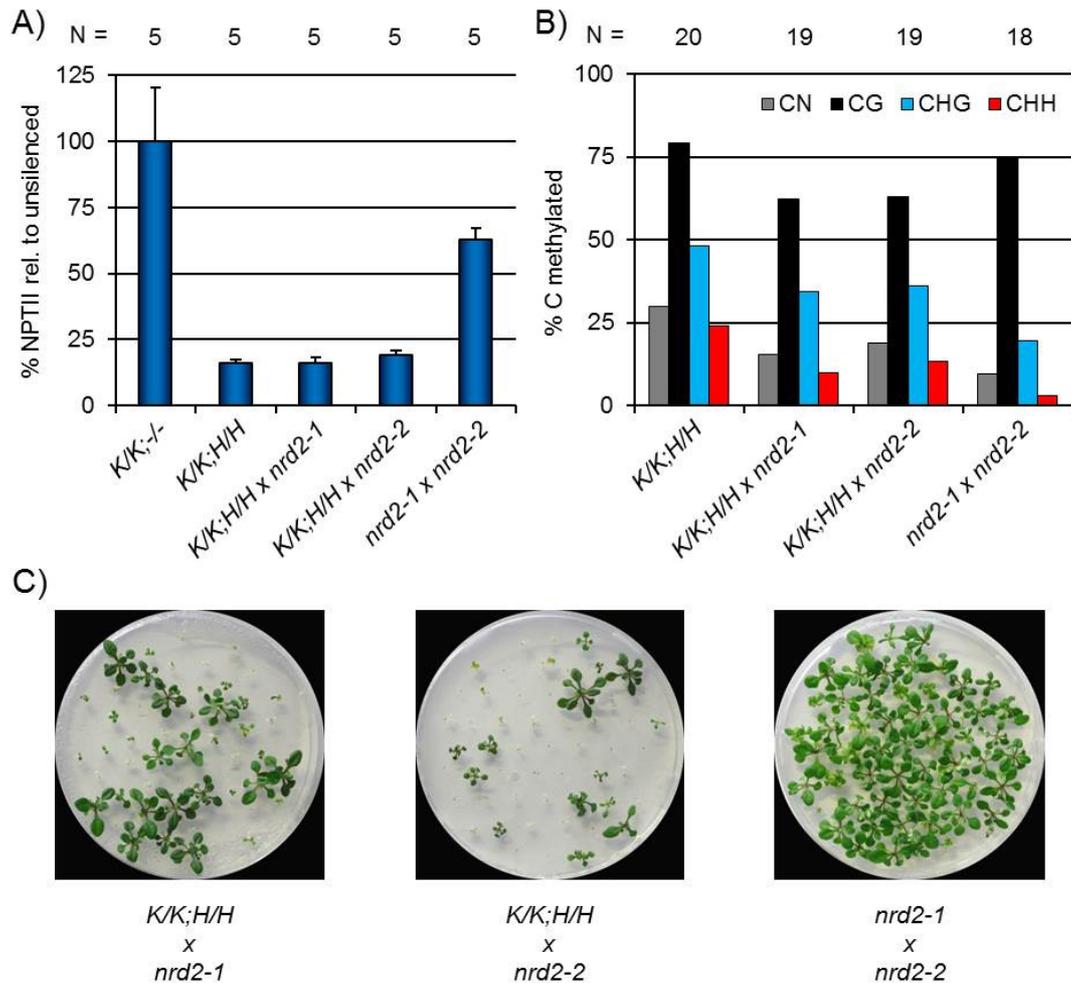

Figure 14: Lack of complementation between *nrd2-1* and *nrd2-2*

A) NPTII ELISA of F₁ progeny of a complementing crosses between *nrd2-1* and *nrd2-2*. Values for comparable *K/K;-/-*, *K/K;H/H* and of F₁ progeny heterozygous for *nrd2* alleles after back crosses to wild type plants are displayed as controls. Protein levels were determined in leaves of 5-week-old plants. Column heights represent mean value, error bars represent standard deviation. The number of plants analyzed is depicted above the diagram. B) DNA methylation at *AtMU1* in F₁ progeny of backcrosses and crosses between *nrd2-1* and *nrd2-2*. The number of clones analyzed per genotype is indicated. C) Segregation of *Kan^R* phenotype in F₂ individuals of after backcrosses (left and mid) and cross of *nrd2-1* and *nrd2-2*.

K/K;H/H individual. Of these SNPs, 132 were found to cause homozygous, non-synonymous mutations in the CDS of protein coding genes, including a G → A mutation at position 3659 in exon 4 of *NRPD2a*. This mutation causes the exchange of glutamate 660 for a lysine (Figure 13E) at protein level. Similar to the previously isolated *nrd2a* alleles, the affected residue is evolutionary conserve among the second-largest subunits of DNA dependent RNA polymerases in *A. thaliana* as well as in those of other eukaryotic organisms (Figure 13 and Figure S3), suggesting a functional importance of the residue. Therefore, candidate 20-12 is considered to harbor another loss-of-function allele of *nrd2a* (*nrd2a-af*) and thus belongs to the *nrd2* complementation group.

However, the genetic verification of this conclusion was not possible due to time constraints within the frame of this thesis.

3.5.4 *NRD3* MUTATIONS ARE ALLELIC TO *DRM2*

Map based cloning approach

To identify the mutation causative for the release of RdTGS in mutant *26-5*, an initial population of 317 M_3F_2 plants was tested on selective GM resulting in an initial mapping population of 34 $\text{Hyg}^R \text{Kan}^R M_3F_2$ individuals. After removal of “false positive” M_3F_2 by analysis of the incidence of the $\text{Hyg}^R \text{Kan}^R$ phenotype in M_3F_3 progeny 32 “true positive” plants remained. These 32 true $\text{Hyg}^R \text{Kan}^R M_3F_2$ plants were genotyped using the GoldenGate assay. Genotyping resulted in the identification of several marker loci located at different chromosomes that were homozygous for the respective Col-0 alleles in a high proportion of the population (Figure 15A). In particular, all plants were found to be homozygous for Col-0 alleles at markers *ILM2-2*, *ILM2-3* and *ILM2-4*,. Furthermore, also at markers *ILM5-2*, *ILM5-3* and *ILM5-4*, all plants were homozygous for Col-0 alleles (Figure 15A). A mapping population of in total 76 true $\text{Hyg}^R \text{Kan}^R M_3F_2$ plants was genotyped with additional markers for chromosome 2 and 5, to further delimitate the areas homozygous for Col-0. This resulted in the identification of a section at chromosome 2 defined by markers *2g02770* (*At2g02770*) and *C2P312504* (*At2g11970*) that covered an area of approx. 4.2 Mb of physical distance (19 cM genetic distance) (data not shown) and a section of 5.1 Mb (23 cM) defined by markers *CER482932* (*At5g06750*) and *C5-7193938* (*At5g21150*) at chromosome 5 (Figure 15B). As mutant *26-5* was mapped to regions different from *nrd1* and *nrd2*, it was assigned to a new complementation group as *nrd3-1*. As the 76 true $\text{Hyg}^R \text{Kan}^R M_3F_2$ plants, represent approximately 10% (76/779) of total screened individuals the presence of a single-locus recessive mutation was anticipated.

No gene involved in RdDM and RdTGS was described so far for the area defined by *2g02770* and *C2P312504* on chromosome 2. However, two gene loci, *DRM2* (*At5g14620*) and *DRM1* (*At5g15380*), relevant for RdDM, are localized between *CER482932* and *C5-7193938* on chromosome 5. *DRM2* is the DNA methyltransferase predominantly responsible for *de novo* DNA methylation and maintenance of methylation in the CHH context in *A. thaliana* (Gao and Jacobsen, 2003), while *DRM1* encodes a *DRM2*-homolog specifically expressed in the egg cell. Although both proteins seem to harbor all elements required for DNA methyltransferase activity, only mutations in *DRM2*

Results

results in a significant reduction of DNA methylation in mature *A. thaliana* leaves (Cao and Jacobsen, 2003; Julien *et al.*, 2012).

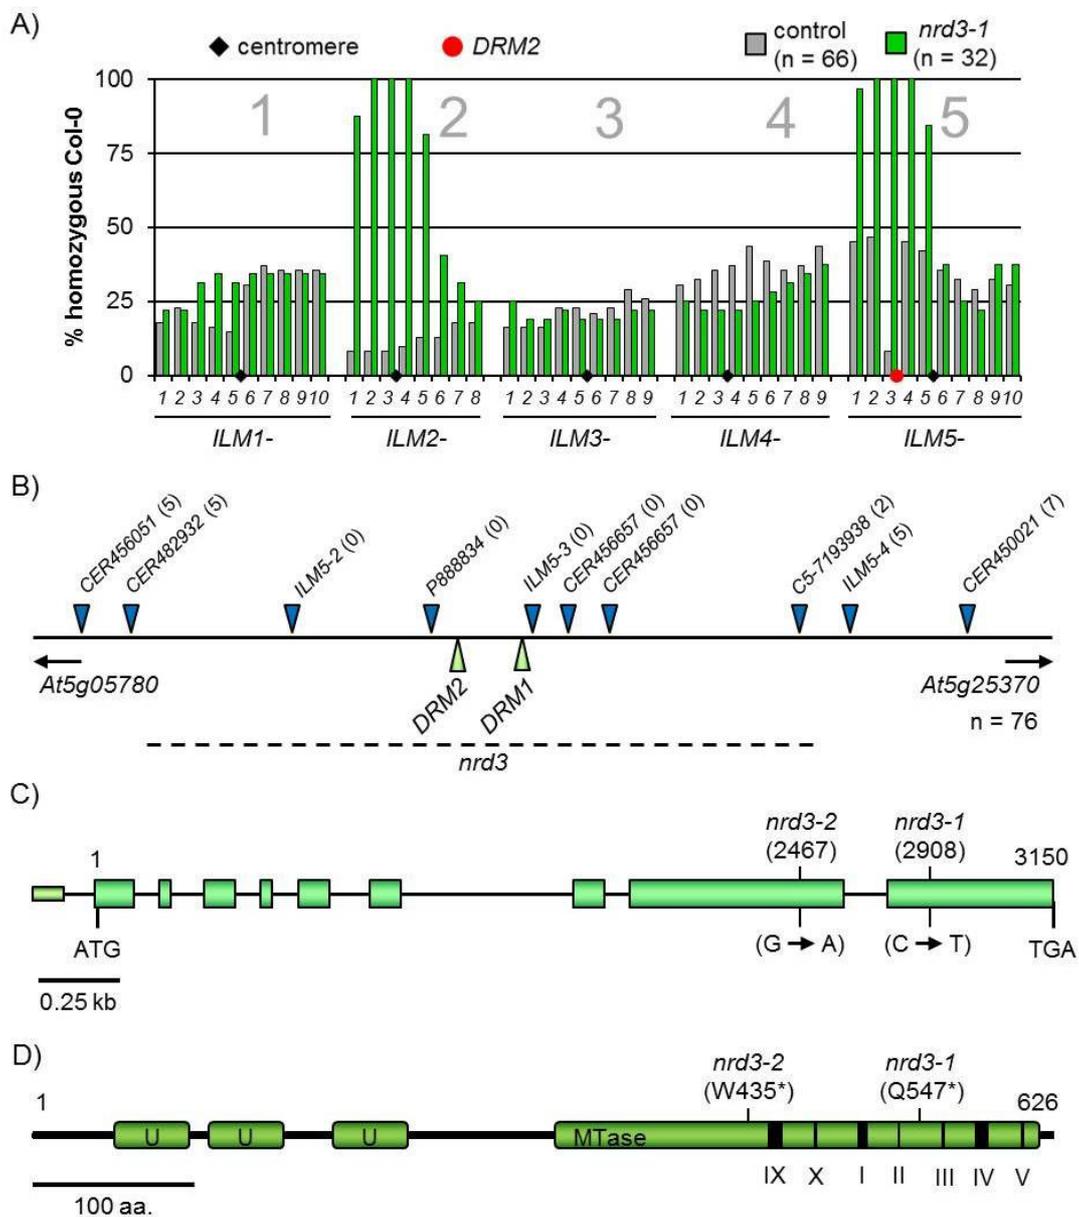

Figure 15: *nrd3*

A) Marker allele incidences in a *Kan^R Hyg^R M₃F₂* mapping population derived from *nrd3-1* as determined by the Illumina GoldenGate assay. B) Fine mapping of the position of *nrd3-1*. Numbers of recombination events among 76 *Kan^R Hyg^R M₃F₂* detected by Indel and CAPS markers are indicated in parenthesis. C) Gene model of *DRM2* (At5g14620). Position of identified nucleotide exchanges in mutant alleles for *nrd3-1* and *nrd3-2* are displayed in parenthesis. Numbers refer to the position in the genomic sequence relative to the first nucleotide of the START codon. D) Protein model of *DRM2*. Positions of premature STOP codons are indicated above symbolized by asterisks. Annotation of UBA domains (U), C-5 cytosine methyltransferase domain (MTase) are displayed. Position of conserved catalytic residues are highlighted as black bars and numbered according to established nomenclature (Henderson *et al.*, 2010).

Sequencing of PCR products amplified from *At5g14620* in five M_3 individuals of *nrd3-1* lead to the identification of a C → T transition in exon 9 at position 2908 causing a nonsense mutation and thus a STOP codon at position 547 of the protein (Figure 15C and D). The resulting truncated protein lacks motives III, IV and V of the methyltransferase domain, which are highly conserved among DNA methyltransferases (Chang et al., 1995; Cao et al., 2000). As mutation of *DRM2* is sufficient to impair *de novo* methylation of transgenes and endogenous loci and the incidence of the Kan^RHyg^R phenotype is consistent with a single causative mutant locus, it is plausible that no further mutation affecting RdTGS and RdDM is present in candidate 26-5 and that the linkage to chromosome 2 observed in marker-based mapping is an artifact, possibly due to chromosomal rearrangements.

Complementation of *nrd3-1* with transgenic *DRM2*

To verify that the causative mutation in *nrd3-1* is allelic to *drm2*, the coding region of *DRM2* under control of its native promoter (*ProDRM2:DRM2*) was amplified from genomic DNA of wild type *A. thaliana* Col-0 via PCR and introduced into *nrd3-1* M_3 plants via *A. tumefaciens* mediated transformation (Figure 16A). In parallel, transformation of *nrd3-1* M_3 plants with the empty binary vector *pCMBL2* (*pCMBL2-EV*) was carried out as control.

Approximately 3×10^4 (*ProDRM2:DRM2*) and 1.5×10^4 (*pCMBL2-EV*), respectively, seeds obtained from floral dip transformation were screened for BASTA^R T₁ transformants. The isolated BASTA^R plants were tested for the presence of the three transgenes via PCR using specific primers. The segregation of the Kan^S phenotype in T₂ progeny of independent primary transformants was assayed for three of the *ProDRM2:DRM2* lines and two of the *pCMBL2-EV* lines obtained. Approximately 220 T₂ seeds per line were germinated on GM containing 200 mg/l kanamycin. For two of the *ProDRM2:DRM2* lines, approx. 75 % of the T₂ seedlings displayed a Kan^S phenotype matching the expected value for a successful complementation by a single locus insertion, whereas the T₂ progeny of the empty vector lines displayed approx. 100% Kan^R phenotype (Figure 16D). Furthermore the amount of NPTII protein in leaves of mature T₂ plants was analyzed in comparison to *nrd3-1* M_4 mutant plants. T₂ progeny grown on soil was screened by PCR for the presence of the *BAR* resistance marker. The amount of NPTII protein in *ProDRM2:DRM2* plants resembled the values found in *K/K;H/H* wild type plants, whereas plants transformed with the empty T-DNA vector displayed NPTII levels similar to M_4 progeny of *nrd3-1* (Figure 16C).

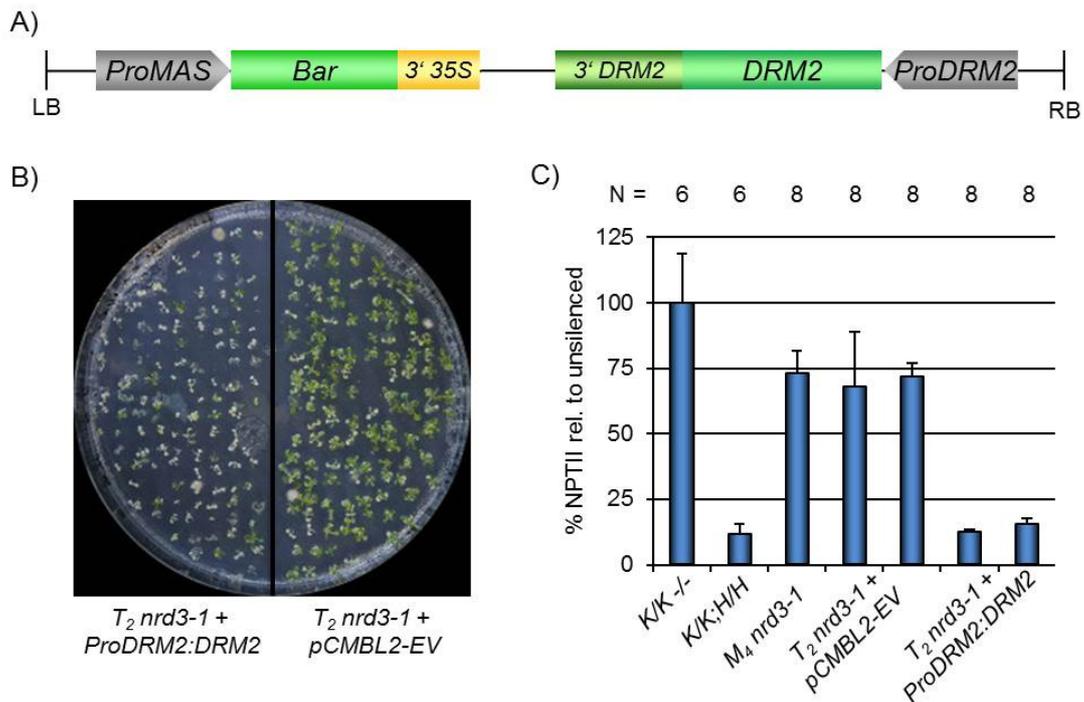

Figure 16: Complementation of *nrd3-1* by *ProDRM2:DRM2*.

A) T-DNA construct used for complementation of *nrd3-1* B) Segregation of Kan^S phenotype in T₂ progeny after introduction of *ProDRM2:DRM2*. Approximately 75% of assayed individuals display the Kan^S phenotype indicating reestablishment of *ProNOS-NPTII* RdTGS and thus the successful complementation of *nrd3-1*. C) NPTII ELISA of T₂ progeny of two independent primary transformants with *ProDRM2:DRM2*, controls T₂ progeny of empty vector transformants, K/K;-/-, K/K:H/H and M₄ *nrd3-1*. Column heights represent mean values, error bars represent standard deviations. Protein levels were determined in leaves of 5-week-old plants. Number of plants assayed is indicated above diagram.

Identification of *nrd3-2* by whole genome sequencing

In 13-14, a mutation in *DRM2* was detected by NGS of DNA from one M₃ plant. In total 47,194,081 reads were obtained, of which 30,158,845 (63.9%) were properly mapped to the *A. thaliana* nuclear genome. On average, every base pair was covered by 22 reads. Analysis of these reads, led to the identification of 3217 SNPs differing from the *A. thaliana* reference sequence. Among the 1071 SNPs exclusively found in mutant 13-14, 80 were found to cause non-synonymous, homozygous mutations in the CDS of protein coding genes. One of these mutations was found at position 2467 (relative to the 1st nucleotide of the START codon) in exon 9 of *DRM2*. The putative nonsense mutation results in a premature STOP codon at position 435 of the protein. Therefore, the predicted protein is lacking all domains conserved in DNA methyltransferases. The presence and homozygous nature of the mutation in M₃ progeny was confirmed by Sanger sequencing of PCR products obtained from *DRM2* in five M₃ individuals of line 13-14. Hence, the causative mutation in 13-14 is very likely allelic to *drm2* and was assigned as second member *nrd3-2* to complementation group *nrd3*. As no verification

by complementing crosses between *nrd3-1* and *nrd3-2* or by transformation with *ProDRM2:DRM2* could be carried out in the context of this thesis due to lack of time, the putative *drm2* loss-of-function allele was designated as *drm2-af*.

3.5.5 *NRD4* IS POTENTIALLY ALLELIC TO *AGO6*

Map based cloning approach

Screening of 634 M_3F_2 plants derived from mutant 1-23 for $Kan^R Hyg^R$ individuals resulted in an initial mapping population of 42 plants. The Genotyping of this population with the help of the GoldenGate assay detected a very high proportion of plants homozygous for Col-0 alleles at markers *ILM5-2* and *ILM5-4* on the upper arm of chromosome 5 (Figure 17). Further genotyping of a total of 128 $Kan^R Hyg^R M_3F_2$ individuals with chromosome 5-specific CAPS marker supported these results. As in case of the $Hyg^R GUS^+ C_3F_2$ control population, significantly fewer plants homozygous for the Col-0 allele were found for marker *ILM5-3* than for the flanking markers *ILM5-2* and *ILM5-4*. However, the difference was more pronounced than in the control population. Segregation of the $Kan^R Hyg^R$ phenotype was assayed in M_3F_3 progeny of individuals heterozygous for all markers tested at chromosome 5. All such individuals were found to be “false positive” and withdrawn from further analysis, resulting in a final mapping population of 117 plants, representing approximately 7.3% of the 1603 plants initially screened for the $Kan^R Hyg^R$ phenotype. This differs significantly (χ^2 -test, $p > 0,01$) from the incidence of 14% $Kan^R Hyg^R$ individuals expected if a single recessive mutation is causative for the resistance phenotype. Sequencing of *DRM2* and *DRM1*, the only loci known to be involved in RdDM located between *ILM5-2* and *ILM5-4*, did not lead to the discovery of any mutations in the CDS or the promoter of these genes. Therefore, it was assumed that a locus previously not described to be involved in RdDM is causative for the release of RdTGS in mutant 1-23. Thus, 1-23 was assigned to the new complementation group *nrd4*. However, a lower peak of enhanced incidence for Col-0 alleles in $Kan^R Hyg^R M_3F_2$ was also observed around marker *ILM2-7* on the lower arm of chromosome 2.

Whole genome sequencing

In parallel, it was attempted to identify the mutated locus causative for the release of the NPTII silencing in *nrd4* by NGS. The Sequencing of the DNA from one M_3 individual of *nrd4* resulted in 69,416,025 reads of which 63,765,878 (91.9%) reads were successfully mapped to the five chromosomes of *A. thaliana*. On average, every base pair was

covered by 49 reads. Processing of these reads resulted in the identification of 3569 SNPs varying from the *A. thaliana* genome reference sequence. Of these SNPs, 1163 were not found in the sequenced *K/K;H/H* control plant. Analysis of these positions resulted in the identification of 66 homozygous SNPs causing non-synonymous mutations in the CDS of protein coding genes (Table S10).

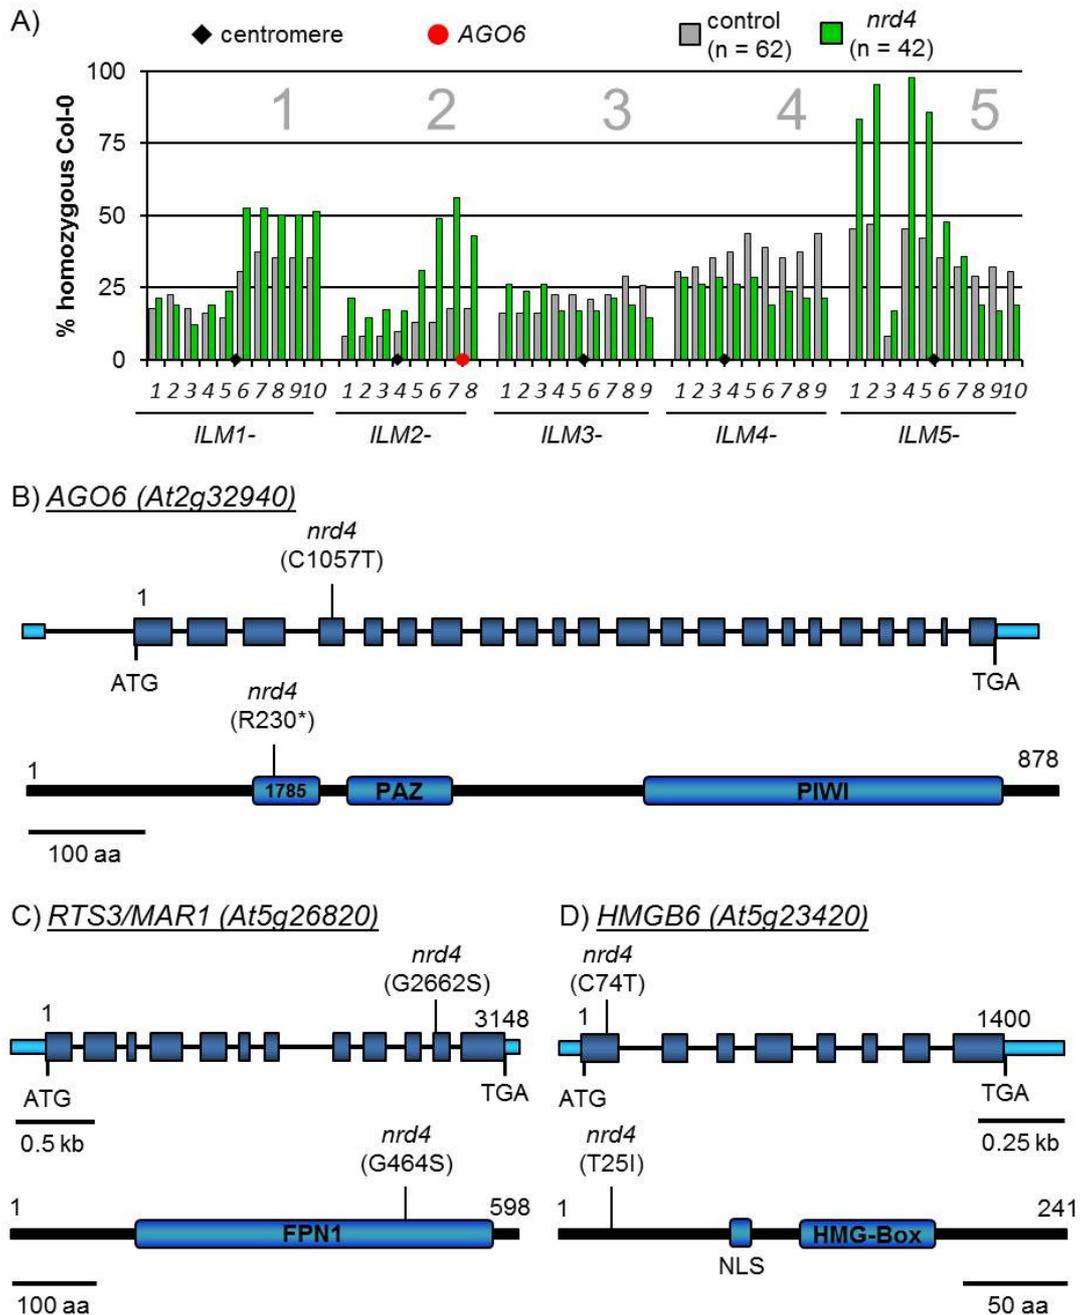

Figure 17: *nrd4*.

A) Marker allele incidences in a Kan^R Hyg^R M₃F₂ population derived from *nrd4* as determined Illumina GoldenGate assay. Displayed data include possible false positive individuals. For genotyping results using an extended mapping population of 117 individuals see Table S6. B – D) Gene and protein models indicating nucleotide and amino acid exchanges presumably contributing to the Kan^R phenotype of *nrd4*. Numbering in gene models is according to the genomic sequence relative to the first bp of the START codon. Conserved proteins domains are indicated. DUF1785 (1785), PIWI/ ARGONAUT/ZWILLE (PAZ), Ferroportin1-like (FPN1), Nuclear localization signal (NLS), High Mobility Group box (HMG-Box).

Among these, 19 were located on chromosome 5 (Table S10). However, none of these mutations affected a gene locus previously described to be involved in RdDM or RdTGS.

Evaluation of the mutant loci for genes listed in the chromatin database (Gendler *et al.*, 2008) (www.chromdb.org) revealed that one mutation affects a gene locus coding for a chromatin-associated protein. This locus (*At5g23420*) codes for HMGB6, one of six HMGB proteins identified in *A. thaliana* (Grasser *et al.*, 2004; Merkle and Grasser, 2011). The identified C → T mutation in the 1st exon at position 74 (relative to the A of the START codon) causes the exchange of threonine 25 for an isoleucine. The residue is part of the extended N-terminal region of HMGB6 which is unique among to the HMGB proteins of *A. thaliana*. Putative HMGB6 homologs of other plant species were identified by BLASTP searches using the full length HMGB6 as query. Protein sequence alignments of the identified homologs revealed no evolutionary conservation of the affected residue (data not shown).

A further mutation present in *nrd4* affected gene *At5g26820* coding for *MAR1/IREG3/RTS3*. Loss of the respective protein can cause resistance to aminoglycoside antibiotics such as kanamycin independent of the presence of transgenic detoxifying enzymes (Aufsatz *et al.*, 2009, Conte *et al.*, 2010).

Further analysis of identified SNPs lead to the identification of a C → T mutation in the 4th exon of *AGO6* (*At2g32940*), a member of the AGO4 clade of *A. thaliana* AGO proteins that was previously described to act in RdDM and RdTGS (Zhang *et al.*, 2007; Havecker *et al.*, 2010; Eun *et al.*, 2011). The nonsense mutation at nucleotide 1057 causes a STOP codon at amino acid position 230 of AGO6, resulting in a predicted protein lacking all domains essential for AGO protein function.

To validate the identified *ago6* mutant allele as causative for the release of RdTGS in *nrd4*, complementation by introduction of an *AGO6* wild type ORF was initiated. However, transformation of M₃ individuals with the complementing T-DNA construct and subsequent analysis of positive transformants could not be completed within the time frame of the work for this thesis.

3.5.6 *NRD5* IS POTENTIALLY ALLELIC TO *DRD1*

Map based cloning

A mapping population of 113 plants, representing approximately 17% of initially 671 Kan^R Hyg^R M₃F₂ individuals derived from M₃ of line 2-11 was genotyped using the GoldenGate

assay to identify the location of the mutation causative for Kan^R Hyg^R phenotype. Genotyping resulted in the observation that all markers located at chromosome 2 were severely enriched for Col-0 alleles compared to the Hyg^R GUS⁺ C₃F₂ control population, with marker *ILM2-5* showing the highest Col-0 allele incidence. However, a higher incidence of the homozygous Col-0 alleles was observed for markers located on the upper arm of chromosome 5 with marker *ILM5-2* and *ILM5-4* showing the highest incidence. Sequencing of *DRM1* and *DRM2* located between *ILM5-2* and *ILM5-4* did not lead to the identification of any mutation in the promoter or the CDS of these genes. Hence, whole genome sequencing was performed to identify the causative mutation in this candidate line.

Whole genome sequencing

NGS of one M₃ individual of *2-11* resulted in 66,747,201 unique reads of which 64,652,780 (96.9%) were properly mapped to sequences of the five *A. thaliana* chromosomes. On average a single base pair was covered by 47 reads. Processing of this reads lead to the identification of 1235 SNPs unique for *2-11*. Of these, 84 SNPs were found to cause homozygous non-synonymous mutations in the CDS of protein coding genes.

A missense mutation was identified in gene *At2g16390* which is located close to marker *ILM2-5*. The gene is coding for DRD1, a SWI/SNF2 chromatin remodeling factor known to be involved in RdTGS and RdDM. The G → A mutation located in the 4th of the gene at position 2870 (relative to the 1st nucleotide of the START codon) causes the exchange of a glycine for an aspartate at position 683 of the protein. The homozygous nature of the mutation was verified by sequencing the PCR products of the respective genomic segment of *drd1* in five M₃ mutant plants. For estimation of a functional impairment caused by the amino acid exchange, protein sequence alignment of SWI2/SNF2 chromatin remodeling factors known and proposed to act in RdDM in *A. thaliana* as well as of putative DRD1 homologs of other plant species were performed. Results indicated a high conservation of the affected residue (Figure 18D), pointing to a role of this residue for functionality of the protein. Thus *2-11* is most likely allelic to *drd1* and represents a member *nrd5* a further complementation group. Due to time constrains, no verification by introduction of a DRD1 wild type ORF was carried out in the frame of this thesis. The putative *drd1* allele was termed *drd1-af*.

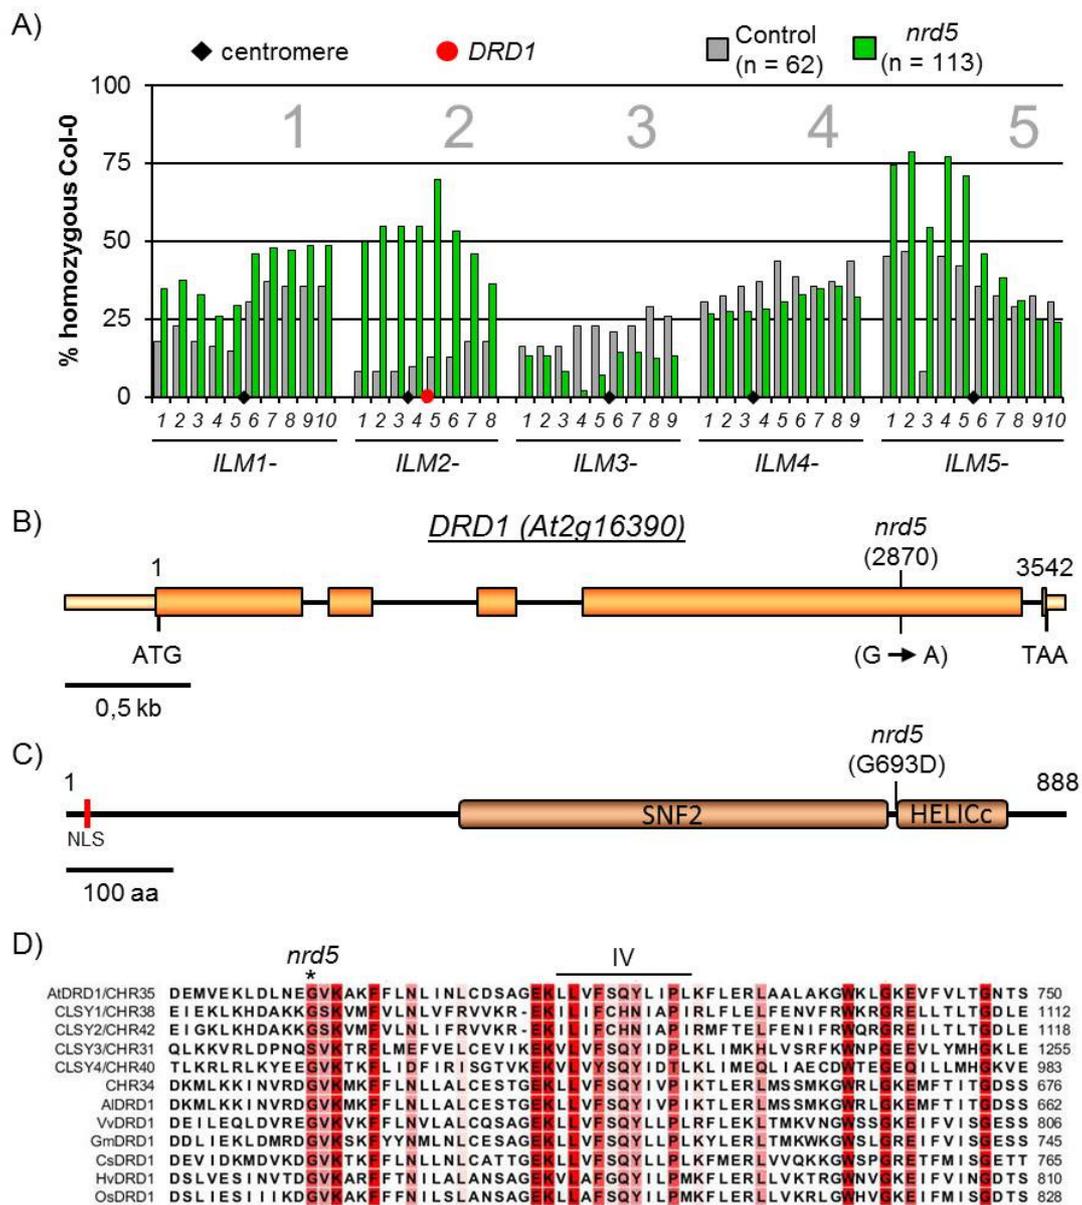

Figure 18: nrd5

A) Marker allele incidences in a Kan^R Hyg^R M₃F₂ population derived from *nrd5* as determined by GoldenGate assay. Values are based on results prior to removal of “false positive” plants. B) Gene model of *DRD1*. Position and nature of the nucleotide change identified by whole genome sequencing is depicted. Numbering is according to the genomic sequence relative to the first nucleotide of the START codon. C) Protein model of DRD1. Conserved domains are indicated. D) Fragment of a protein sequence alignment of SWI2/SNF2-like chromatin remodeling factors of *A. thaliana*, *Arabidopsis lyrata* (Al) *Vitis vinifera* (Vv), *Glycine max* (Gm), *Cucumis sativa* (Cs) *Hordeum vulgare* (Hv), Conserved residues are highlighted in red, The amino acid residue affected in *nrd5* is marked by an asterisk. For the identification of DRD1-like proteins, a full length putative DRD1 protein sequence was used. The ClustalW2 algorithm was used for alignment.

3.5.7 NRD6 IS POTENTIALLY ALLELIC TO NRPE1

The mutations causative for the release of transcriptional silencing in mutants 9-20 and 11-12 were identified by NGS of one M₃ individual each. Sequencing of genomic DNA of 9-20 and 11-12 resulted in 57,551,632 and 43,326,794 unique reads, respectively. Of

these 53,350,327 (92.7%) and 35,668,197 (82.3%), respectively, were successfully mapped to the chromosomes of *A. thaliana* resulting in approximately 39-fold (9-20) and 26-fold (11-12) coverage of the genome.

In line 9-20, 997 SNPs not found in the sequenced non-mutagenized *K/K;H/H* individual were identified. 79 of these caused homozygous, non-synonymous mutations in CDS of protein coding genes (Table S12). One of these mutations represents a G → A exchange at position 4036 in the 9th exon of *At2g40030*. This gene encodes for NRPE1, the largest catalytic subunit of Pol V, which indispensable for RdDM (Pontier *et al.*, 2005; Kanno *et al.*, 2005). The identified mutation leads to the exchange of glycine 937 for an aspartate in the RNA polymerase domain of the protein. Genotyping of a mapping population of 17 Kan^R Hyg^R M₃F₂ plants derived from line 9-20 lead to the identification of a high incidence of the Col-0 allele for marker *ILM2-8* located physically close to *At2g40030* (*NRPE1*). This further supports the assumption that the identified *nrpe1* allele is causative for the release of RdTGS and RdDM in this line. Therefore, line 9-20 presumably contains with *nrd6-1* an allele of a 6th complementation group of the current screen.

To estimate the impact of the amino acid exchange on the functionality of the NRPE1 protein, putative homologous proteins in other plant species were identified by BLASTP search using full length *A. thaliana* NRPE1 protein sequence. Sequence alignments of the identified homologs revealed a complete conservation for the mutated residue in the analyzed proteins (Figure 19). In line 11-12, 1069 unique SNPs that were not present in the sequenced non-mutagenized *K/K;H/H* individual were identified. 103 of these caused homologous, non-synonymous mutations in the CDS of protein coding genes (Table S13). As in line 9-20, one mutation causes a single nucleotide exchange in *At2g40030* (*NRPE1*). The C → T exchange at position 5495 in exon 13 of the gene causes a non-sense mutation leading to a premature STOP codon. The resulting protein is deficient of the C-terminal domain containing the reiterated GW/WG motives (AGO-hook domain) that was reported to be crucial for the interaction with AGO proteins. Therefore line 11-12 is as *nrd6-2* presumably the second member of the *nrd6* complementation group. Due to time constrains, no verification by transgenic introduction of a *NRPE1* wild type ORF or complementing crosses between *nrd6-1* and *nrd6-2* was carried out in the frame of this thesis. The putative loss-of-function alleles were termed *nrpe1-af1* and *nrpe1-af2*.

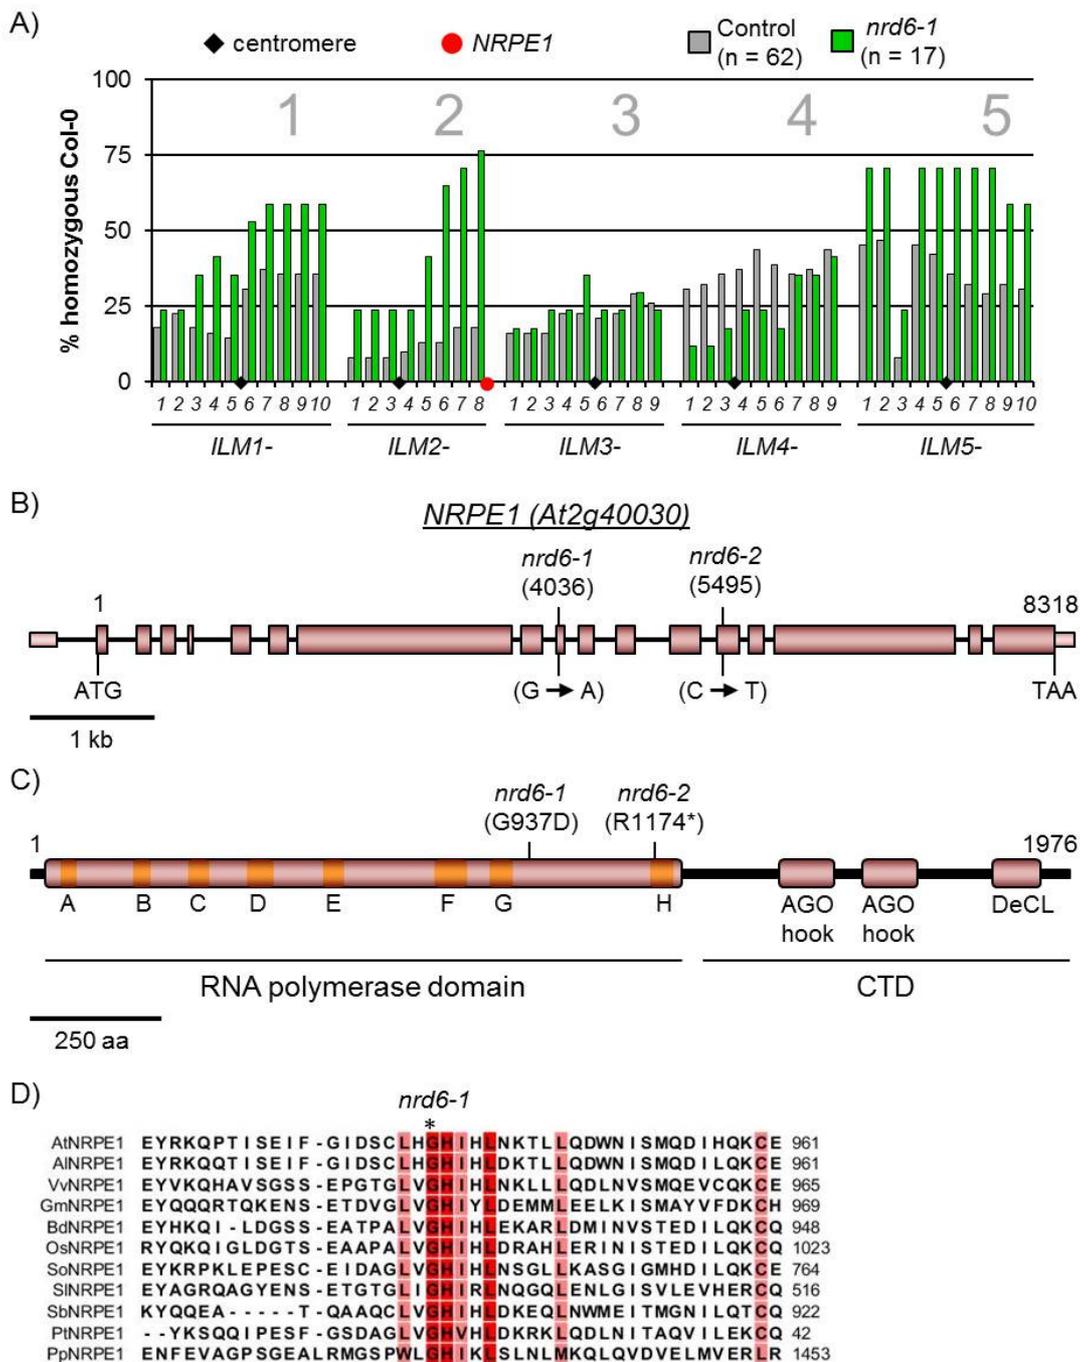

Figure 19: nrd6

Depicted are results prior to removal of putative “false positive” individuals. B) Gen model of *NRPE1*. Positions and nature of identified nucleotide are indicated. Numbering is according to the genomic sequence relative to the first bp of the START codon. C) Protein model of *NRPE1* showing positions of the predicted amino acid exchange and premature STOP codon, respectively. Conserved domains and motives are according to Pontier et al., (2005). D) Protein sequence alignments of *A. thaliana* *NRPE1* (*AtNRPE1*) and putative *NRPE1* homologs of *Arabidopsis lyrate* (*Al*), *Vitis vinifera* (*Vv*), *Glycine max* (*Gm*), *Brachipodium distachion* (*Bd*), *Oryza sativa* (*Os*), *Spinachia oleracea* (*So*), *Solanum lycopersicon* (*Sl*), *Populus trichocarpa* (*Pt*), *Physcomytrella patens* (*Pp*).

3.6 DE NOVO ASSEMBLY OF THE *ARABIDOPSIS THALIANA* GENOME

As described above, in several mapping approaches (*nrd4*, *nrd5* and *nrd6-1*) an unanticipated low incidence of homozygosity for Col-0 alleles was observed for markers *ILM5-3* and *C5-5609978* when genotyping F₂ individuals containing the *K* and *H* transgenes derived from *K/K;H/H* x *Ler* crosses. This gave the impression of a “coldspot” of recombination in this area on chromosome 5. A notable exception was observed for *nrd3-1*, for which two peaks of high incidence of Col-0 alleles were observed, one in the same area of chromosome 5 and a second one on chromosome 2.

It is well known that, chromosomal rearrangements, like inversions, might occur upon *A. tumefaciens* mediated T-DNA transfer and have the potential to negatively affect recombination frequencies if present in heterozygous state (Andolfatto *et al.*, 2001; Kirkpatrick, 2010; Nacry *et al.*, 1998). To address the presumption that chromosomal rearrangements might cause the reduced recombination rate at marker *ILM5-3*, the sequence information obtained from whole genome sequencing was used to perform *de novo* assembly of the genome of the sequenced non-mutagenized *K/K;H/H* control plant as well as of M₃ *nrd3-2* and M₃ *nrd4* plants. Staggered assembly of the NGS reads lead to the formation of longer assembly units (contigs). The identification of two contigs that map to the same chromosome but show discordance in size and orientation between their 5' and 3' ends would indicate an inversion event (Korbel *et al.*, 2007; Le Scouarnec *et al.*, 2012). Mapping of contigs of *K/K;H/H* resulted in the identification of contigs 2597 and 2882 which map to the upper arm of chromosome 5. These contigs are 93 kb and 80 kb in length, respectively. However, their respective ends map approx. 800 kb apart. While the break point of contig 2597 was mapped to the intergenic region between loci *At5g13130* and *At5g13140*, the break point of contig 2882 maps between *At5g17200* and *At5g17210* (Figure 20). Pairwise alignment of the intergenic sequences led to the identification of two highly similar (96%) sequences of approx. 760 bp that are in sense / antisense orientation to each other. Notably, no such contigs were obtained during read assembly for mutant M₃ *nrd3-2*, making it conceivable that the respective rearranged version of chromosome 5 is segregating among line *K/K;H/H*-derived plants.

However, attempts to confirm this inversion by PCR using primers specific for flanking regions of the assumed break points were inconclusive (data not shown), leaving it possible that chromosome rearrangements are more complex.

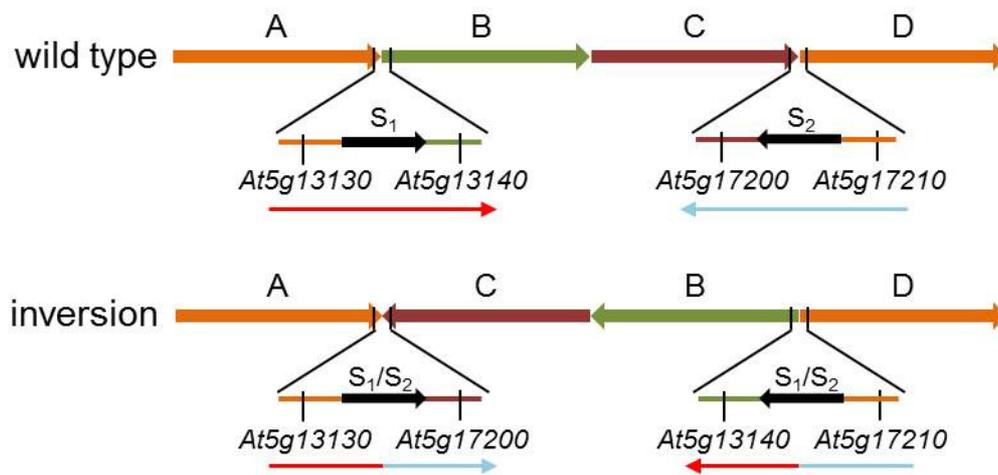

Figure 20: A putative inversion at chromosome 5

Order of loci in wild type plants according to the *A. thaliana* Col-0 genome reference sequence (upper panel) and in (some) transgenic *K/K;H/H* wild type plants as suggested by *de novo* assembly of NGS reads of the sequenced non-mutagenized *K/K;H/H* and *M₃ nrd4* individuals (lower panel). Locations and composition of highly similar sequences at break points are indicated (S₁, S₂, S_{1/S₂}).

4 DISCUSSION

To the present day, the forward genetic screen carried out in this thesis lead to the identification of ten independent *nrd* mutants which were assigned to six distinct complementation groups. Analysis of the DNA methylation at endogenous sequences revealed that the mutations in these mutants cause substantial reduction of methylation in non-CG context at known RdDM targets. The candidate gene loci in four of these *nrd* mutants were identified by map based cloning, whereas putative candidate gene loci in the remaining six *nrd* lines were identified by NGS. The mutations were found to affect components of the RdDM pathway previously isolated in other forward genetic screens (Kanno *et al.*, 2004; Kanno *et al.*, 2008; Eun *et al.*, 2012).

4.1 SILENCING OF THE EMPLOYED TRANSGENE SYSTEM DEPENDS ON THE RDDM PATHWAY

A transgene system targeting a *ProNOS-NPTII* reporter construct as employed in the current work was used in a previous genetic study of RdTGS of a transgene locus in *A. thaliana* (Aufsatz *et al.*, 2002a). No mutation in RdDM factors were identified in this screen, but rather several *met1* and *hda6* alleles were isolated (Aufsatz *et al.*, 2002a; Aufsatz *et al.*, 2004). Based on the sole identification of factors involved in maintenance of CG methylation instead of RdDM components, it was suggested that the relatively high density of sites in the CG context in the *ProNOS* leads to a particular role of the maintenance pathway for silencing of *ProNOS* controlled transgenes (Eun *et al.*, 2012). Interestingly, neither *met1* nor *hda6* were identified in our screen so far. Instead, all identified mutant alleles affect loci known to be involved in RdDM downstream of siRNA biogenesis. These loci were previously identified in other transgene systems involving different reporter gene promoters. This indicates that non-CG methylation is necessary for the stable silencing of the *ProNOS-NPTII* gene in the used *K* transgene. The most striking difference between both screens might be the copy number of the *K* transgene. While several complete and incomplete *K* insertion events were reported for the silencing system used by Aufsatz *et al.*, (2002a, 2002b), a single copy transgene particularly sensitive to RdDM was used for the screen performed in this thesis (Schubert *et al.*, 2004; Fischer *et al.*, 2008). Therefore, the different outcomes might be based on the different importance of diverse silencing mechanisms in dependence of the *ProNOS*

copy number rather than on sequence composition of the *ProNOS per se*. A further factor influencing the mechanism necessary for transcriptional silencing might be the local chromatin environment into which the transgene is inserted.

4.2 DEEPER SCREENING MIGHT RESULT IN THE IDENTIFICATION OF ADDITIONAL COMPLEMENTATION GROUPS

Due to the rather small number of isolated mutants releasing RdTGS and RdDM with three out of six complementation groups containing a single member so far, it is plausible that our screen is not yet saturated. This is further supported by the results of other forward genetic screens using similar transgene systems which managed to identify a wider spectrum of components of the RdDM pathway (Kanno *et al.*, 2008; Eun *et al.*, 2012 and references herein).

Thus further screening of our transgene system potentially result in the identification of new alleles of most of these and possibly even additional components. Designation of these mutations by map based cloning approaches might be challenged by the assumed translocation event affecting chromosome 2 and 5 as most of these loci are located at chromosome 2. Nevertheless, the availability of new NGS-based methods for mutation mapping might help to solve these shortcomings (Hartwig *et al.*, 2012).

4.3 MUTATION OF EVOLUTIONARY CONSERVED RESIDUES IN POL V SUBUNITS IMPAIR RDDM

In addition to the expected set of subunits for the common eukaryotic DNA-dependent RNA polymerases I, II and III, the annotation of the *A. thaliana* genome indicates additional genes which encode atypical largest and second-largest subunits for which plant specific functions were predicted (Arabidopsis genome initiative, 2000). It is now well established that these proteins represent the catalytic subunits of the two plant specific DNA-dependent polymerases Pol IV and Pol V, which are essential in RdTGS via RdDM (Herr *et al.*, 2005; Onodera *et al.*, 2005; Pontier *et al.*, 2005; Kanno *et al.*, 2005). Analysis of the subunit composition revealed that both complexes are constituted of 12 subunits, some of which shared with Pol II (Ream *et al.*, 2006; Luo and Hall, 2007; Law *et al.*, 2011; Eun *et al.*, 2012), supporting the assumption that Pol IV and Pol V evolved from Pol II (Ream *et al.*, 2006; Luo and Hall, 2007). In the course of this thesis mutations, in the subunit NRPD2a, common to Pol IV and V, and in the Pol V specific subunit NRPE1 were identified.

4.3.1 THE EFFECT OF MISSENSE MUTATIONS IN THE SECOND-LARGEST SUBUNIT

In *A. thaliana* two closely related genes putatively encoding a second-largest subunits of Pol IV and Pol V, *NRPD2a* and *NRPD2b*, were identified. Both genes were found to be transcribed (Pontier *et al.*, 2005). However, only *nrpd2a* mutants affect RdDM and only *NRPD2a* was identified to encode a functional subunit of Pol IV and Pol V (Herr *et al.*, 2005; Ream *et al.*, 2008). Therefore, *NRPD2b* is considered to be most likely a transcribed pseudogene (Pontier *et al.*, 2005).

In the course of the work for this thesis three *nrpd2a/nrpd2a* alleles were identified. All identified alleles contain missense mutations resulting in exchanges of amino acids which are conserved among the second largest subunits of DNA dependent RNA polymerases of *A. thaliana* and in case of *nrpd2a-54 (nrd2-1)*, in virtually all pro- and eukaryotic DNA-dependent RNA polymerases.

The DNA methylation in non-CG context was found to be severely reduced at *TARGET-ProNOS*, *AtSN1*, *MEA-ISR* in all isolated *nrpd2a* mutants. Furthermore, DNA methylation analysis of *AtMU1* performed in *nrpd2a-54 (nrd2-1)* and *nrpd2a-55 (nrd2-2)* also revealed a significant reduction in non-CG context methylation. The observed reduction of non-CG methylation at *AtSN1* and *MEA-ISR* is in good agreement with results previously published for *nrpd2a* and *nrpd2a nrpd2b* double mutants (Kanno *et al.*, 2005a; Onodera *et al.*, 2005; Lopez *et al.*, 2011; X Zhang *et al.*, 2007b; Greenberg *et al.*, 2011).

The slight differences in non-CG methylation at *AtSN1* and *MEA-ISR* in *nrpd2a-54* and *nrpd2a-55* compared to data published for *nrpd2a* and *nrpd2a nrpd2b* mutants might be due to differences in the growth conditions or plant age between both studies. Furthermore, although it is considered as a pseudogene a slight influence of the *NRPD2b* locus cannot be excluded.

The elevated NPTII amounts observed in F₁ individuals from complementing crosses between *nrpd2a-54* and *nrpd2a-55*, but not in F₁ from backcrosses of the respective mutant lines to *K/K;H/H* wild type plants and the almost 100% incidence of the Kan^R phenotype in F₂ progeny of complementing crosses, but only about 25% of Kan^R plants in F₂ progeny of backcrosses confirmed the allelic nature of the mutations in these lines. In addition, no re-establishment of CHH methylation at *AtMU1* was observed in the analyzed F₁ individual of *nrpd2a-54 x nrpd2a-55* crosses compared to the respective M₄ individuals. Analysis of F₁ progeny of the backcrosses showed clearly more methylation in the CHH context, but wild type levels were not reached. These results have to be

regarded with caution, as half of the analyzed F₁ genome descended from the *K/K;H/H* wild type parent and therefore displayed wild type methylation levels from the beginning. A possible explanation would be that re-methylation at hypomethylated *AtMU1* in the presence of functional *NRPD2a* in F₁ from backcrosses is a slow process that takes longer than one generation. Such delayed methylation in RdDM has already been observed at transgenic targets (Fischer *et al.*, 2008). With hindsight, analysis of F₁ individuals of crosses between *nrpd2a* alleles and mutants affected in RdDM factors which are not part of the Pol IV and Pol V complexes, such as *drm2*, *rdr2* or *ago4* might have been a more informative option.

The mutation in *nrpd2a-54* affects the second glutamate residue of the GEME motif which is conserved in virtually all pro- and eukaryotic DNA dependent RNA polymerases known (Cromie *et al.*, 1999, Sidorenko *et al.*, 2010). Sidorenko *et al.*, (2010) reported an virtually identical mutation in the GEME motive in *MEDIATOR OF PARAMUTATION2* (*MOP2*), a homolog of *NRPD2a* in *Zea mays*. The *mop2-1* mutation was reported to affect paramutation at some investigated loci such as *b1* in a dominant manner. However no indication was found for dominance of the *nrpd2a-54* mutation. In the mapping approach, 11% Kan^R Hyg^R M₃F₂ were counted in progeny derived from the *nrpd2a-54* cross to *Ler*, which is well consistent with the 14% expected for a recessive mutation. Furthermore, as revealed by the persisting non-CG methylation at *AtMU1* in backcrosses of *nrpd2a-54* to *K/K;H/H*, no dominant effect is observed for this endogenous target as well. The assumption is further supported by an *nrpd2a* allele reported by Kanno *et al.*, (2005) in which a mutation causing an amino acid exchange in the GEME motif is recessive as well. However, as only a small number of targets were analyzed in this study and the dominant effect observed in *mop2-1* was reported to be locus specific, the existence of loci in *A. thaliana*, that are affected in a dominant fashion cannot be entirely excluded. Whole genome bisulfite sequencing of wild type plants and such heterozygous for the *nrpd2a/nrpd2a-54* allele would be of interest to clarify this issue. Loci, hypomethylated in plants that are heterozygous for the *nrpd2a/nrpd2a-54* would be likely candidate loci that are affected in a dominant way. Nevertheless, a locus-specific slow re-methylation of hypomethylated endogenous RdDM targets as discussed above for *AtMU1* would always offer an alternative explanation for a seemingly dominant mutation effect.

In contrast to *nrpd2a-54* and *nrpd2a-55*, the *nrpd2a* allele *nrpd2a-af* (*nrd2-3*) was not confirmed by complementation. However, the mutation of also a highly conserved residue makes it a very likely loss-of-function allele.

4.3.2 PUTATIVE LOSS-OF-FUNCTION ALLELES OF POL V LARGEST SUBUNIT

The most prominent difference between NRPE1, the largest subunit of Pol V, and the largest subunits of the other nuclear DNA-dependent RNA polymerases Pol I, Pol II, Pol III and Pol IV is an extended C-terminal domain (CTD) (Haag *et al.*, 2012). The Pol V CTD is characterized by a WG/GW-rich domain which is known to physically interact with AGO4, AGO6 and AGO9 as well as with SPT5L and is essential for the locus-specific recruitment of the above AGO proteins to chromatin (Li *et al.*, 2006; El-Shami *et al.*, 2007; Havecker *et al.*, 2010).

In the context of the work for this thesis, NGS of two mutant lines lead to the identification of mutations affecting NRPE1. The analysis of the DNA methylation status of endogenous RdDM targets in these lines revealed a severe decrease of non-CG methylation at all tested loci. The reduction of non-CG methylation in *AtSN1* determined by methylation-sensitive restriction cleavage using HaeIII was previously published for the alleles *nrpe1-1* (Pontier *et al.*, 2005), *nrpe1-11* (Lopez *et al.*, 2011) and an unnumbered *nrpe1* allele (Kanno *et al.*, 2005a). Furthermore, He *et al.*, (2007) provide *AtSN1* bisulfite sequencing data for the *nrpe1-11* allele. All these data are in good agreement with the results obtained for *nrpe1* candidates in this thesis work (He *et al.*, 2007; He *et al.*, 2009). Bisulfite sequencing data for *MEA-ISR* previously reported for *nrpe1-11* in accession Col-0 and an unnumbered *nrpe1* allele in accession C-24 reveal a similar loss of DNA methylation in non CG-context as observed for *nrpe1* alleles identified in our screen (He *et al.*, 2007; Liu *et al.*, 2011; Greenberg *et al.*, 2010).

Due to time constrains, complementation tests of these mutants were not carried out in the frame of this thesis. Furthermore, a possible effect of the mutation on the protein level was not assayed due to lack of appropriate antibodies. Therefore, the identified mutant alleles *nrpe1-af1* (*nrd6-1*) and *nrpe1-af2* (*nrd6-2*) still need to be considered as likely candidates. Nevertheless, the assumption that they are causative for the release of silencing and DNA methylation is supported by two further facts. First, genotyping of the *nrpe1-af1* mapping population reveal a high incidence of homozygosity for the Col-0 allele towards the end of the lower arm of chromosome 2, the location of the NRPE1 gene. Second, the amino acids affected by the mutations in the two alleles seem to be

conserved among NRPE1 homologs of multiple plant species, which hints to their functional importance. In contrast to *nrpe1-af1*, no genotyping of a mapping population was carried out for *nrpe1-af2*. The presence of a premature STOP codon in *nrpe1-af2* makes it a likely null allele.

4.4 TWO NEW NON-SENSE ALLELES IN DOMAINS REARRANGED METHYLTRANSFERASE 2

The initial studies to address the roles of the members of the *DRM* gene family in DNA methylation in *A. thaliana* found *DRM2* but failed to detect *DRM1* mRNA in vegetative tissues (Cao and Jacobsen, 2002). Moreover, CHH maintenance as well as *de novo* methylation were found to be affected in *drm2* single and *drm1 drm2* double mutants, but not in *drm1* single mutant plants (Cao and Jacobsen, 2002; Cao and Jacobsen 2003). This led to the conclusion that *DRM2* encodes the only actively expressed DNA methyltransferase in *de novo* methylation and that *DRM1* is supposedly a pseudogene. However, the recently discovered egg cell-specific expression of *DRM1* and the reduced CHH methylation level at *MEA-ISR* during early embryo development in *drm1* mutants amend the earlier assumption, showing that *DRM1* is functional in a well-defined developmental stage (Jullien *et al.*, 2012).

Two *drm2* alleles were identified during the work for this thesis. Both mutations create premature STOP codons. In case of the *drm2-8 (nrd3-1)* allele, which was confirmed by complementation, translation of the mRNA would most likely result in a non-functional protein lacking important motifs of the DMTase domain. As the loss of half of the catalytic motifs is accompanied by release of RdTGS, the loss of the entire DMTase domain in proteins derived from the second allele *drm2-af (nrd3-2)* certainly would cause a release of silencing, too.

4.5 A PUTATIVE LOSS-OF-FUNCTION ALLELE IN *DRD1*

SWI2/SNF2 ATPases are chromatin associated enzymes that confer chromatin remodeling by repositioning of nucleosomes (Coe *et al.*, 1994). While binding to the targeted DNA is conferred in an ATP-independent manner, release of the DNA strand requires hydrolysis of the tri-phosphate (Vignali *et al.*, 2000). SWI2/SNF2 ATPases are characterized by two similar protein domains which contain seven conserved sequence motifs involved in binding and coordinated processing of ATP and DNA substrates (Smith and Peterson, 2005).

The SWI2/SNF2 chromatin remodeling factor-like proteins DDM1, CLASSY1 and DRD1 are known components of the of DNA methylation machinery in *A. thaliana*. While DDM1 mainly acts in co-operation with MET1 in maintenance of methylation in CG context, CLSY1 and DRD1 are components of the RdDM pathway. CLSY1 associates with Pol IV and RDR2. Hence, a function in early steps of RdDM is suggested (Smith *et al.*, 2007; Law *et al.*, 2011). By contrast, DRD1 acts in RdDM downstream of siRNA production. This assumption was originally made based on the observation that *drd1* mutants do not decrease the amount of 24 nt siRNAs derived from a constitutively transcribed *IR* of the α' promoter (Kanno *et al.*, 2004). In a follow up study, it was shown that DRD1 is not only involved in RdDM but also in the establishment of *de novo* methylation and has an active role in removal of CG methylation after the silencing signal is lost (Kanno *et al.*, 2005b).

In the work for this thesis, a missense mutation in *drd1* was identified by NGS. The mutation causes a G \rightarrow D exchange at position 693 of the protein. At all analyzed endogenous RdDM target sequences, a severe reduction of DNA methylation in the CHH context was observed comparable to the non-sense allele *drd1-6* (Kanno *et al.*, 2004; Chan *et al.*, 2006). While the data published for *MEA-ISR* are almost identical to my data, the results for *AtSN1* slightly differ in the way that substantially more non-CG methylation is retained in *drd1-af* (*nrd5-1*) than in *drd1-6*. This might be due to the different nature of the analyzed alleles or due to differences in experimental details. On the other hand, *drd1-af* exhibits the most severe reduction of DNA methylation at the *TARGET-ProNOS* of all identified mutant lines. This coincides with the highest amount of NPTII protein measured.

Due to time constrains, the causative role of the *drd1-af* mutation was not confirmed by complementation. However, several observations support the assumption that the mutation is essential for the release of TGS of the *NPTII* gene in this line. First, genotyping of the Kan^R Hyg^R M₃F₂ population revealed a high incidence of Col-0 homozygosity at markers close to the *DRD1* encoding gene locus. Moreover, the amount of *ProNOS* derived siRNAs was not found to be reduced but rather slightly increased in *drd1-af*. These observations are in agreement with those previously made for *drd1* null mutants in a similar transgene system (Kanno *et al.*, 2004). These authors reported a severe reduction of non-CG methylation at the α' promoter, which coincides with a strong release of GFP silencing. The observed release was stronger than that observed in *nrdp2a/nrpe2a* and *nrpe1* alleles isolated in the same screen (Kanno *et al.*, 2004).

Protein sequence alignments using the full length hydrolase domain (i.e. the SNF2 domain and DEXDc domain) of several SNF2-like proteins show that G693 is well conserved in the SNF2-like proteins that are known and/or implied to be involved RdDM in *A. thaliana*, pointing to its functional importance. G693 is in vicinity to the conserved motive IV which is involved in DNA binding. Its exchange might induce conformational or environmental changes that might impair this interaction. A further possibility is the impairment of viable protein-protein interactions, e.g. to NRPE1, DMS3 or RDM1.

4.6 AGO6 MIGHT BE NECESSARY FOR SILENCING IN TRANSGENE SYSTEMS

One of the identified mutants lines, *nrd4-1*, clearly differs from the remaining ones in respect to release of *NPTII* silencing and *TARGET-ProNOS* methylation. In this line only a partial release of the *NPTII* silencing was observed. Furthermore, substantial amounts of CHH and CHG context remained at the *TARGET-ProNOS*.

The analysis of the NGS data from a *nrd4-1* plant lead to the identification of a nonsense mutation in locus *At2g32940*, which encodes the RdDM factor AGO6. NULL alleles of *AGO6* were previously isolated in two independent forward genetic screens (Zheng *et al.*, 2007; Eun *et al.*, 2011). Both studies report an incomplete release of the expression of transgenic reporter genes in these mutants, which comes along with notable levels of CHH methylation remaining at the transgenic promoters. The premature STOP in *ago6-af* (*nrd4-1*) causes the truncation of the protein after 320 amino acids. The resulting protein would lack the PAZ and PIWI domains which are of vital importance for functionality of AGO proteins (Vaucheret, 2008). Therefore, it is valid to assume that the identified *ago6-af* is a null allele. Nevertheless, due to missing complementation it still has to be considered as a likely candidate.

In contrast to the *TARGET-ProNOS*, which retained substantial non-CG context methylation, the analyzed endogenous RdDM targets *AtSN1*, *MEA-ISR* and *AtMU1* exhibit DNA methylation levels which resemble those of other RdDM mutants identified in this thesis. Further, the results obtained for *AtSN1* and *MEA-ISR* are in line with those published for allele *ago6-1*. However, a rather mild effect on the CHH methylation in *AtSN1* was reported for the T-DNA insertion allele *ago6-2* (Zheng *et al.*, 2007; Havecker *et al.*, 2010). These deviant results may be due to differences between the *A. thaliana* accessions in which the analyzed alleles were obtained, the analyzed plant tissues or the

number of generation for which the analyzed plants had been homozygous for the respective *ago6* alleles.

The differences between the methylation levels of transgenic and endogenous sequences might be based on the different sources of dsRNA. While the synthesis of initial endogenous dsRNA depends on the activity of Pol IV and RDR2, dsRNA formation in the transgene system involving transcribed IRs depends on the activity of Pol II. Furthermore, the massive and constitutive transcription of the *ProNOS-IR* and comparably high amounts of *ProNOS* siRNAs in the transgene system might contribute to the observed effect.

AGO6 as well as AGO4, AGO8 and AGO9 belong to a clade of *A.thaliana* AGO proteins that bind 24 nt siRNAs and confer chromatin modifications. Within this clade, AGO4, AGO8 and AGO9 are closely related, while AGO6 shows higher sequence variation (Vaucheret, 2008). AGO4 is ubiquitarily expressed (Zilberman *et al.*, 2003; Havecker *et al.*, 2010; Eun *et al.*, 2011), expression of AGO6 is restricted to apical meristems and the connecting vascular tissue (Havecker *et al.*, 2010; Eun *et al.*, 2011). AGO9 expression seems to be limited to ovules, anthers and the seed coat (Havecker *et al.*, 2010; Olmedo-Monfil *et al.*, 2010, Calaroco and Martienssen, 2011). AGO8 is considered to be a pseudogene (Vaucheret, 2008). It is assumed, that AGO4 clade proteins act at least partially redundant (Havecker *et al.*, 2010). Based on this assumption the observed decrease of CHH methylation levels at *AtSN1*, *MEA-ISR* and *AtMU1* is striking as it suggests that the expression of AGO4 in leaf tissue is not sufficient to complement the lack of AGO6 in *ago6* mutants at these loci. This points to a possible functional non-redundancy between AGO6 and AGO4. The inability of a *ProAGO4:AGO6* construct to complement an *ago4-3* mutant further supports this idea (Havecker *et al.*, 2010). Possibly, the activity of AGO6 in the apical meristems is necessary to establish certain prerequisites, e.g. basal levels of DNA methylation which facilitate efficient recruitment of AGO4 to certain loci. However, this hypothesis will need experimental proof.

4.7 SECOND SITE MUTATION MIGHT INFLUENCE KAN^R IN AGO6

Although the identified *ago6* mutation represents a very likely candidate to be responsible for the observed silencing release, results from genotyping of the Kan^R Hyg^R M₃F₂ mapping population are somewhat inconsistent with this assumption. Indeed, they revealed a markedly increase of homozygosity for Col-0 alleles at markers physically close to the *AGO6* locus. However, a much higher incidence of homozygosity for the Col-

0 allele was found for markers at the upper arm of chromosome 5. Together with the observed incidence of approximately 7.5 % for the Kan^R Hyg^R phenotype in the M₃F₂ generation for the *nrd4-1*, this observation suggests a second mutation in this line that contributes to the Kan^R phenotype. Two mutated loci that might contribute to the Kan^R Hyg^R phenotype were identified by NGS on the upper arm of chromosome 5.

4.7.1 A HMG-BOX CONTAINING PROTEIN MIGHT AFFECT TRANSCRIPTIONAL SILENCING

One of these mutations affects *HMGB6*, the gene encoding a nuclear chromatin-associated protein of unknown function, which is able to bind to DNA *via* its HMG-box domain *in vitro* (Grasser *et al.*, 2004). Due to its association with chromatin, involvement of HMGB6 in epigenetic processes, like RdDM, is plausible. The identified mutation would cause the exchange of threonine 25 (T25) for an isoleucine in the N-terminal domain. Protein sequence alignments with sequences of putative HMGB6 homologs identified by BLASTP searches revealed no evolutionary conservation of the residue, leaving its significance open.

4.7.2 RdDM INDEPENDENT MUTATION MIGHT CONTRIBUTE TO THE KAN^R PHENOTYPE OF AGO6.

In addition to the identified putative *ago6* and *hmgb6* alleles, a mutation in locus *At5g26820* was identified in *nrd4-1*. This locus encodes RTS3/MAR1, a chloroplast protein with similarity to the iron regulated transporters IREG1 and IREG2. Two previous studies reported that loss-of-function *rts3/mar1* allele can confer increased resistance to kanamycin, most likely due to the impaired antibiotics uptake (Aufsatz *et al.*, 2009; Conte *et al.*, 2009).

The G464S mutation identified in *nrd4-1*, affects a residue which is invariant between RTS3/MAR1 homologs in *A. thaliana*, *O. sativa* and *V. vinifera* (Conte *et al.*, 2009). Therefore, its mutation might cause a non-functional protein that contributes to the Kan^R phenotype in a RdDM independent manner. This would explain the high incidence of homozygosity for Col-0 alleles at the upper arm of chromosome 5 observed in Kan^R Hyg^R M₃F₂ individuals. To test if the *rts3/mar1* allele influences the segregation of the Kan^R Hyg^R phenotype, genotyping of mapping populations obtained from homozygous *rts3/mar1* single mutants would be necessary.

4.8 A POINT MUTATION IN THE XH DOMAIN OF IDN2 CAUSES RELEASE OF RDTGS

In the genome of *A. thaliana* 14 gene loci encoding proteins with sequence homology to SUPPRESSOR OF SILENCING (SGS3) and its rice homolog gene X1 that fell into three clades were identified (Qin *et al.*, 2009; Xie *et al.*, 2012). SGS3-like proteins are characterized by various combinations of the XS domain, the XH domain, a coiled coil domain (CC) and a zinc finger domain (ZnF) (Bateman, 2002). IDN2 harbors all of these domains. *In vitro* studies showed the ability of IDN2 to bind dsRNA with 2 nt 5'-overhangs and with blunt ends via its XS domain. It is assumed that this preference is conferred by special structural elements present in the RNA recognition motif of the XS domain. The vital role of IDN2 in RdDM was identified in a screen for T-DNA insertion mutants incapable to methylate a FWA transgene *de novo*. Additional *idn2* alleles were identified in independent forward genetic screens for suppressors of RdDM (Ausin *et al.*, 2009; Zheng *et al.*, 2010; Xie *et al.*, 2012; Lorcovice *et al.*, 2012; Finke *et al.*, 2012b).

In the progress of work for this thesis, an *idn2* allele was identified in one of the silencing suppressor mutants and was termed *idn2-8 (nrd1)*. The CHH context methylation levels at the *TARGET-ProNOS* were found severely decrease in *idn2-8* and resembled those of other silencing suppressor mutants obtained in this screen. The reduction of *TARGET-ProNOS* methylation was accompanied by a markedly increase of NPTII protein levels which resembled those observed of the identified *nrd2a/nrpe2a*, *drm2* and *nrpe1* alleles, but was somewhat lower than those of the *drd1* allele and the non-silenced wild type *K/K;-/-* control. The persistence of reduced NPTII expression might be explained by the residual CG and CHG context methylation at the *TARGET-ProNOS*, which might contributes to the silencing effect and is absent in non-silenced *K/K;-/-* plants. The nearly complete loss of CHH context methylation at *AtSN1*, CHH and CHG methylation at *MEA-ISR* and the markedly reduction of CHH methylation at *AtMU1* in identified *idn2-8* allele is similar to the results previously reported for the null alleles *idn2-1* and *idn2-5/rdm12-1*, respectively (Ausin *et al.*, 2009; Zhang *et al.*, 2012; Ausin *et al.*, 2012). Therefore, it was suggest that the identified point mutation in the XH domain renders *idn2-8* into an effective null allele. This was confirmed onto introduction of an IDN2 wild type ORF into *idn2-8* which complements the mutant phenotype.

As *idn2-8* mRNA level were not reduced compared to wild type, the mutant effect is not due to transcript degradation but most likely due to post-translational issues. IDN2 is supposed to act in higher order complexes consisting of IDN2 homodimers or

heterodimers formed with closely related IDP/FDM/IDNL proteins (Zhang *et al.*, 2012; Ausin *et al.*, 2012; Xie *et al.*, 2012, Wierzbicki *et al.*, 2012). It was shown that the homodimerization is necessary for the activity of IDN2 in RdDM and that it depends on the presence of the CC domain, whereas the XH domain is necessary for the formation of heterodimers (Ausin *et al.*, 2012; Zheng *et al.*, 2012; Zhu *et al.*, 2012). In *idn2-8* the formation of these higher order complexes might be compromised due to the structural alterations in the XH domain.

4.9 IDN2 ACTS DOWNSTREAM OF siRNA FORMATION

As the RNA species fitting the binding characteristics of IDN2 occur more than once in the RdDM pathway, the position of *IDN2* in the RdDM pathway was a matter of debate in the initial publications. Based on analogy to the cooperation of SGS3 and RDR6 to generate dsRNA in PTGS, IDN2 has been proposed to cooperate in the RDR2-dependent production of dsRNA from a Pol IV-generated single stranded transcript (Zhang *et al.*, 2010). In an alternative model, IDN2 is involved in stabilizing siRNA-p5-RNA duplexes in the process of guiding DRM2-mediated DNA methylation (Ausin *et al.*, 2009). As formation of *ProNOS* 24nt siRNAs is conferred by Pol II-dependent transcription of an inverted repeat, the RdDM in this system works according to a linear rather than circular pathway (Figure 21). It was previously shown that generation of primary siRNAs and the establishment of RdDM are independent of Pol IV and RDR2. Like in the isolated *nprpd2a-55* mutant, siRNA formation was also not compromised in *idn2-8*. However, the CHH context methylation at the *TARGET-ProNOS* was severely affected by the *idn2-8* mutation. Thus, *idn2-8* needs to act downstream of the siRNA formation in RdDM (Finke *et al.*, 2012b). This assumption is in agreement with an only partial reduction of 24 siRNAs, derived from endogenous RdDM targets such as *AtSN1 MEA-ISR* and *AtMU1* observed in other *idn2/rdm12/dms10* mutant, while a marked impact on CHH and CHG context methylation was observed (Ausin *et al.*, 2009; Zheng *et al.*, 2010; Zhang *et al.*, 2012).

The assumption is further supported by *in vitro* experiment with the IDN2-interacting protein FDM1/IDP1/IDNL1 which showed physical interaction with AGO4 but not with RDR2 and by the reported binding of IDN2 to p5-RNAs (Zhu *et al.*, 2012; Xie *et al.*, 2012).

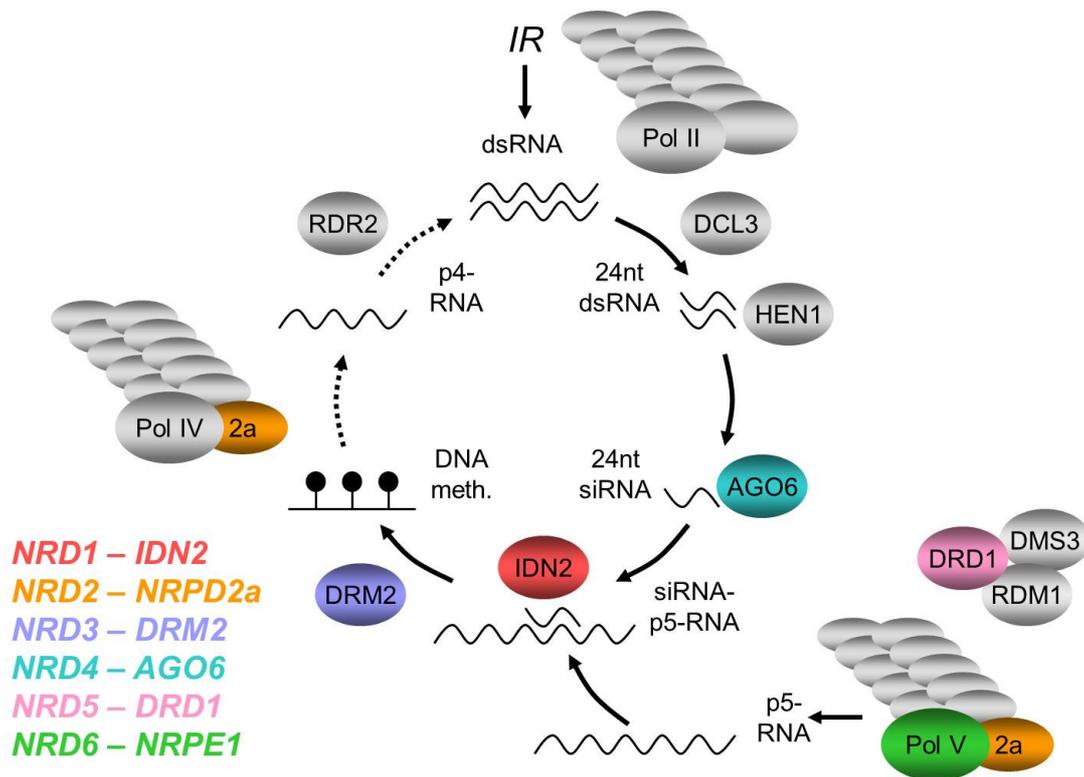

Figure 21: Genetic model of RdTGS in the transgene system.

RdTGS in the transgene system is independent of the Pol IV part of the pathway (dotted arrow) as transcription of an inverted repeat (IR) by Pol II leads to the formation of the dsRNA substrate of DCL3. Therefore RdTGS in this “shortcut” –pathway (solid arrows) depends on factors downstream of the siRNA formation. Factors identified in our screen with at least one allele are highlighted.

4.10 DNA METHYLATION AT *IGN* SEQUENCES AND *BASHO210*

In the progress of the work for this thesis, several less well characterized endogenous sequences were analyzed in respect to their DNA methylation status by methylation-sensitive restriction cleavage and / or bisulfite sequencing in a subset of the isolated mutants. The analyzed sequences were *IGN5*, *IGN23*, *IGN25* and *BASHO210*.

4.10.1 DNA METHYLATION AT *IGN5*, *IGN23* AND *IGN25*

The evaluation of CHH context methylation at *IGN5*, *IGN23*, *IGN25* in transgenic, but otherwise wild type plants with the help of methylation-sensitive restriction confirmed previously published results (Wierzbicki *et al.*, 2009; Rowley *et al.*, 2010; Lorkovic *et al.*, 2012). Bisulfite sequencing of *IGN5* in transgenic *K/K;H/H* wild type plants revealed a high amount of CG, CHG and CHH context methylation at this sequence. The obtained values for CG and CHG context methylation at this locus are in line with results published by others (Greenberg *et al.*, 2011). However, according to Greenberg *et al.*, (2010), less than 10 % of CHH context cytosines are methylated in wild type *A. thaliana* accession Col-0 plants. By contrast, approximately 30 % of cytosines in CHH context

were found to be methylated in *K/K;H/H* individuals. As both studies do not differ in analyzed accession or the analyzed sequence, the most likely explanation for these differences are variations in plant age, analyzed tissue or growth conditions.

Bisulfite sequencing of locus *IGN23* in wild type tissue indicated substantial DNA methylation in all sequence contexts in *K/K;H/H* individuals also outside of the two *HaeIII* restriction sites. These data are contradicted by a recent report, which could not detect any CHH context methylation at the *IGN23* locus in Col-0 plants (Wierzbicki *et al.*, 2012). In the study by Wierzbicki *et al.*, (2012) NGS of bisulfite treated genomic DNA was used to assay genome wide DNA methylation. The criteria used to define methylated and unmethylated sequences might be causative for the consideration that *IGN23* is unmethylated.

The results for *IGN5* methylation in the assayed alleles of *idn2*, *drm2*, *drd1* and *nrpe1* are in agreement with previously reported data for other mutant alleles of these loci (Lorkovic *et al.*, 2012; Wierzbicki *et al.*, 2009; Rowley *et al.*, 2010; Greenberg *et al.*, 2011). The effect of *nrpd2a* mutations on the DNA methylation at *IGN5* was not assayed previously. However, the observed decrease of CHH context methylation in *nrpd2a-54* is in agreement with the function of the protein in the Pol V complex. In contrast to these mutants, almost wild type level of DNA methylation at *IGN5* was observed in *ago6-af*. This is a striking difference compared to the other endogenous targets, in which the reduction in CHH methylation resembles the one in other mutants. This hints to a functional redundant protein, able to establish DNA methylation at this site in absence of *AGO6*.

4.10.2 THE RDDM PATHWAY ACTS AT *BASHO210*

In addition to the established RdDM targets, *BASHO210*, which was previously not described to be targeted by RdDM, was analyzed *via* bisulfite sequencing.. Sequencing of the 5'-part of the sense strand of *BASHO210* in wild type plants revealed substantial DNA methylation in all sequence contexts. While the observed levels of CG context methylation are in rather good agreement with published whole genome bisulfite sequencing data, the high levels of CHG and CHH context methylation were not reported by others (Stroud *et al.*, 2012). However, the high amounts of CHH context methylation which are especially enriched around the CTRR motif of *BASHO210* are in line with the high abundance of 24 nt siRNA which correspond to this locus (Lister *et al.*, 2008). The severely reduced CHH methylation levels in *idn2-8*, *nrpd2a/nrpe2a-54*, *drm2-8* and *ago6-*

Discussion

af confirm the assumption that CHH context methylation at *BASHO210* depends on the RdDM pathway.

5 CONCLUSIONS

The results obtained in this work lead to the main conclusions:

1. The two component transgene system used in this thesis is suitable to identify components of the RdDM pathway in a forward genetic screen.
2. RdDM in the used transgene system is independent of Pol IV activity but requires a functional Pol V complex.
3. The member of the AGO4 clade of *A. thaliana* AGO proteins might have only limited functional redundancy and AGO6 might be necessary for efficient DNA methylation by AGO4..
4. IDN2 acts downstream of the generation of siRNAs.
5. The rolling circle DNA transposon *BASHO210* is targeted by the RdDM pathway.

6 OUTLOOK

1. To test whether the mutations in *nRPD2a-af*, *drm2-af*, *ago6-af*, *drd1-af*, *nrpe1-af1* and *nrpe1-af2* are causative for the release of silencing, crosses with other loss-of-function alleles or complementation with wild type ORFs has to be carried out.
2. To address the question if mutations in the GEME motif of NRPD2a might affect some endogenous loci in a dominant way, comparison of whole genome bisulfite sequencing analysis of plants heterozygous for *nRPD2a-54* and *K/K;H/H* wild type individuals would be suitable.
3. To test if the meristem specific activity of AGO6 is a prerequisite for efficient AGO4 activity, DNA methylation at endogenous targets in *ago6* mutants expressing a *ProAGO6:AGO4* construct should be carried out. Another important test for the involvement of AGO4 would be introgression of an *ago4* mutation into the transgene system used.
4. The fact that similar transgene systems identified a large number of RdDM factors and are supposedly saturated suggests that the potential of the used silencing systems to identify new RdDM factors almost reached its limits. To identify new, potentially functional redundant RdDM factors, affinity purification experiments coupled with mass spectrometric analysis might be carried out.
5. While there is meanwhile good insight into the genetic requirements for the establishment of RdDM, the knowledge concerning the mechanisms that prevent sequences being targeted by RdDM are rather poorly understood. A forward genetic screen *via* “enhancers of silencing” mutants would allow an approach to this.

7 SUMMARY

The aim of this work was the genetic identification and functional characterization of factors involved in RNA-directed transcriptional gene silencing (RdTGS) *via* induced loss-of-function mutants in *A. thaliana*. To isolate these, a transgene system was used in which two copies of the *NOPALINE SYNTHASE* promoter (*ProNOS*), arranged as an inverted repeat are constitutively transcribed. The resulting RNA mediates *in trans* hypermethylation of an unlinked *ProNOS* copy and hence the stable transcriptional repression of a *NPTII* reporter gene, resulting in a kanamycin-sensitive phenotype in wild type individuals.

Batches of M₂ seeds from ethyl methanesulfonate (EMS) mutagenesis of the transgenic line were screened for individuals displaying re-established kanamycin resistance (Kan^R). To confirm the release of *NPTII* silencing, *NPTII* protein levels in Kan^R mutants were analyzed using ELISA. Furthermore, DNA methylation patterns of the transgenic *ProNOS* as well as of several endogenous sequences were analyzed.

The genes affected by mutations causing a release of *NPTII silencing* in the isolated *no rna-directed transcriptional silencing* (*nrd*) mutants were determined by map based cloning and next generation sequencing. The *nrd* mutants could be grouped into six putative complementation groups: *nrd1/idn2*, *nrd2/nrpd2a*, *nrd3/drm2*, *nrd4/ago6*, *nrd5/drd1* and *nrd6/nrpe1*.

Nrd1 and *nrd3* were confirmed to be *idn2* and *drm2* loss-of-function alleles, respectively, by introduction of transgenes carrying wild type alleles of the respective candidate genes which resulted in reestablishment of RdTGS of the *NPTII* gene. The identity of *nrd2* as *nrpd2a* was checked in crosses between independent lines *nrd2-1* and *nrd2-2* both carrying mutations in *NRPD2a*. Unchanged *NPTII* levels and persistent DNA hypomethylation of an endogenous target in F₁ progeny confirmed that the defective *nrpd2a* alleles are indeed causing the release of silencing.

Furthermore, based on Northern analysis of *ProNOS*-derived siRNAs, it was concluded that *IDN2* most likely acts downstream of siRNA formation in RdTGS.

8 ZUSAMMENFASSUNG

Das Ziel dieser Arbeit war die Identifizierung und funktionelle Charakterisierung von Komponenten die am RNA-vermittelten transkriptionellen Silencing und an der RNA-vermittelten DNA-Methylierung im Modelorganismus *A. thaliana* beteiligt sind. Dazu wurde ein Transgensystem verwendet in dem zwei, als *inverted repeat* angeordnete Kopien des *NOPALINSYNTASE* Promoters (*ProNOS*) konstitutiv transkribiert werden. Die resultierende RNA vermittelt die Hypermethylierung einer weiteren, ungekoppelten Kopie des *ProNOS* in trans. Dadurch wird die Expression des Kanamycinresistenzgens *NEOMYCIN PHOSPHOTRANSFERASE II (NPTII)* unterdrückt. Die resultierenden Wildtyppflanzen sind trotz des *NPTII* Gens empfindlich gegenüber Kanamycin.

Die M₂ Generation von mittels EMS mutagenisierter transgener Samen, wurde auf Individuen getestet, die Resistenz gegenüber Kanamycin aufwiesen. Um die Aufhebung des transkriptionellen Silencings in den Kanamycin-resistenten Linien zu bestätigen, wurde die Menge des NPTII Proteins mittels ELISA bestimmt. Darüber hinaus wurden die DNA Methylierungsmuster des transgenen *ProNOS* sowie mehrerer endogener Sequenzen analysiert.

Die mutierten Gene, die für die Aufhebung des NPTII-Silencings in den isolierten *no rna-directed transcriptional silencing (nrd)* Mutanten verantwortlich waren, wurden mittels *Map-based Cloning* und *Next Generation Sequencing* identifiziert. Die *nrd* Mutanten konnten so in die sechs putative Komplementationsgruppen *nrd1/idn2*, *nrd2/nrpd2a*, *nrd3/drm2*, *nrd4/ago6*, *nrd5/drd1* and *nrd6/nrpe1* eingeordnet werden.

Durch Einbringen eines Wildtyp Transgens des jeweiligen Kandidatengenes das zur Reetablierung des NPTII Silencings führte, wurde bestätigt, dass *nrd1* und *nrd3-1* loss-of-function Allele von *IDN2* bzw. *DRM2* sind, die für die Aufhebung des Silencings verantwortlich waren. Die unverändert hohen Mengen an NPTII Protein sowie andauernde DNA Hypomethylierung endogener Sequenzen in F₁ Individuen aus Kreuzung von *nrd2-1* mit *nrd2-2*, bestätigten dass es sich bei diesen Mutanten um nicht funktionelle Allele von *nrpd2a* handelt.

Da *nrd1/idn2* keine merklichen Verringerung der vom *ProNOS-IR* abgeleiteten 24 nt siRNAs aufwies, wurde geschlossen, dass IDN2 nach der siRNA Synthese von Bedeutung im RdDM ist.

Figure S2: Analyzed sequences of *AtSN1*, *MEA-ISR*, *AtMU1* and *AtCOPIA4*.

Cytosines analyzed by bisulfite sequencing are marked in black (CG), cyan (CHG) and red (CHH).

Figure S3: Protein sequence alignments of second-largest subunits of DNA dependent RNA polymerases.
 Proteins of *Schizosaccharomyces pombe* (Sp), *Drosophila melanogaster* (Dm), *Neurospora crassa* (Nc), *Mus musculus* (Mm), *Caenorhabditis elegans* (Ce), *Dictyostelium discoideum* (Dd). ClustalW2 was used for alignments

Table S1: Primer used for detection of transgenes

Target	Primer Name	Sequence (5' → 3')	Product Size (bp)

Table S6: Genotyping results of the extended mapping population of *nrd4*

The allele incidences of homozygous Col-0 (%C), Ler (%L) and the heterozygous state (%H) for all chromosome 5 specific markers tested in the total mapping population of 117 Kan^R Hyg^R M₃F₂ plants are displayed.

EIDESSTATTLICHE ERKLÄRUNG

Hiermit erkläre ich an Eides statt, dass diese Dissertation von mir bisher weder der Naturwissenschaftlichen Fakultät I der Martin-Luther-Universität Halle-Wittenberg noch einer anderen wissenschaftlichen Einrichtung zum Zweck der Promotion eingereicht wurde.

Ich erkläre ferner, dass ich diese Arbeit selbständig und nur unter Zuhilfenahme der angegebenen Hilfsmittel und Literatur angefertigt und wörtlich oder inhaltlich entnommene Stellen sind als solche kenntlich gemacht habe.

Datum:

Unterschrift:

Andreas Finke
